SYNOPSIS. *Solanum* section *Pteroidea* is a small group of ten species of Neotropical primary forest herbs and vines. The group is treated in this monograph as a unit for convenience, but cladistic analysis shows that it is almost certainly not monophyletic. The ten species are therefore placed in two monophyletic species groups: the *Solanum ternatum* species group, defined by its woody vining habit and large flowers, and the *Solanum mite* species group, defined by its conical rugose fruits and ovoid-reniform seeds with distinctive testal morphology. The history of nomenclature and composition of section *Pteroidea* s.l. are discussed. Illustrations and distribution maps are provided and photographs of several of the species show characters of the flowers, fruits, and seeds.

INTRODUCTION

Although it is one of the five or six largest genera of flowering plants, little monographic work has been done in *Solanum* L. (Solanaceae) (see D'Arcy, 1991). Taxonomic research effort has been concen-

trated on groups of economic importance, such as potatoes, tomatoes, morellas, and the spiny solanums. The genus is diverse, with some 1000 or more valid species (D'Arcy, 1991), but monographs do not exist for the majority of species groups in *Solanum*. As part of an ongoing research programme into the taxonomy and phylogeny of non-spiny solanums (see Knapp, 1986a; Knapp, 1989; Knapp,

1991a) we have investigated the small, primarily rainforest species of section *Pteroidea* with the aim of determining the monophyly of the group and the species boundaries within it. The section, whose members are characterized by a scorpioid cyme inflorescence which is axillary in position, is quite heterogeneous, and has apparently no close relatives (see p.33). It is clear from our analyses that the section as treated here is not strictly monophyletic and can be divided into two groups. We have called these groups the *Solanum mite* species group and the *Solanum ternatum* species group, following the convention of Whalen (1984). The true nature of the relationships between these two monophyletic lineages will only become clear with a large scale analysis of all non-spiny solanums. Several potential sister groups have been identified; these will be treated in future monographs, and larger scale relationships tested as more monophyletic groups are identified.

TAXONOMIC AND NOMENCLATURAL HISTORY

Solanum is most species rich in the New World tropics and subtropics, and thus many of the taxa have been described relatively recently. The last comprehensive treatment of the genus was by Dunal (1852) and while 900 species were treated in the *Prodromus*, at least 4000 specific epithets exist for *Solanum* at present. By convention and for convenience *Solanum* is usually divided into two main groups, the spiny solanums (subgenus *Leptostemonum*) and the non-spiny solanums (the rest: subgenera *Solanum*, *Brevantherum*, *Bassovia*, and *Potatoe* – D'Arcy, 1972, see Table 1). Taxonomy of non-spiny solanums has long been confused, and there is considerable disagreement as to monophyly within that portion of the genus. For a detailed history of the taxonomy of *Solanum* both before and after Dunal (1852) see Knapp (1989, 1991a) and Bohs (1994). Knapp (1989) also provides a list of recent monographs of sections of *Solanum*, to which can be added a monograph of *Solanum* section *Allophysllum* (Bohs, 1990) and the genus *Cyphomandra* (Bohs, 1994; now with all epithets transferred to *Solanum*, see Bohs, 1995).

Table 1 Characters used to define the major Neotropical subgenera of *Solanum* (after D'Arcy, 1972).

<i>Solanum</i> c. 1500–2000 species	
subgenus <i>Solanum</i>	Stout anthers, simple hairs, no spines
subgenus <i>Bassovia</i>	Stout anthers, simple hairs, pinnate leaves, axillary inflorescences, pointed fruits
subgenus <i>Brevantherum</i>	Stout anthers, entire leaves, dendritic or stellate hairs
subgenus <i>Potatoe</i>	Scandent species or herbs, pinnate leaves usually with interstitial leaflets, lateral inflorescences, articulated pedicels
subgenus <i>Leptostemonum</i>	Tapering anthers, stellate hairs, almost always with prickles

History of section *Pteroidea*

The first species of section *Pteroidea* to be described was *Solanum anceps* (as *Bassovia sylvatica*), described by Aublet (1775) from what is now French Guiana. Several more species were described by Ruiz & Pavón (1799) from collections made in Peru (*S. anceps*, *S. conicum*, *S. diffusum*, *S. incurvum*, *S. mite*, *S. ternatum*). Ruiz & Pavón noted the similarity between these taxa, and commented upon it in the *Flora peruviana et chilensis* (1799). In his *Histoire*

naturelle, médicale et économique de Solanum, Dunal (1813) attempted to treat taxonomically all known species of *Solanum* in a hierarchical fashion. He divided the genus into a series of nested groups, marked by different symbols (for a discussion of these and their significance to sectional nomenclature in *Solanum* see Knapp, 1983). The group composed of the species of section *Pteroidea* was explicitly given sectional rank ('la section désignée sous le nom *Pteroidea*') by Dunal, one of the few groups of taxa to be assigned rank in his 1813 monograph. In his section *Pteroidea* Dunal (1813) grouped together species sharing the following characters: '*Foliis impari-pinnatis; foliolis integerrimis acuminatis; pedunculis axillaris aggregatis, petiolis brevioribus. PTEROIDEA.*' The simple-leaved species (see Morphology for a discussion of the nature of leaf division in section *Pteroidea*) were not considered related to the pinnate-leaved species by Dunal (1813), and were placed in a heterogeneous group, with species now placed in either the genus *Lycianthes* or *Solanum* section *Geminata* (sensu lato, see Knapp, 1986a). In 1816, Dunal again grouped the pinnate-leaved species of section *Pteroidea* together, adding *S. seaforthianum* (now recognized as a member of section *Jasminosolanum*) to the group. He did, however, recognize the similarities of the simple-leaved taxa, and put them in a group of their own, but without rank. In his *General system of gardening and botany*, one of the best compendia of flowering plants known at the time, George Don (1838) basically followed Dunal in separating the simple and pinnate species, but he put the pinnate taxa in his subsection *Potatoe* with the potatoes and their relatives, while the simple-leaved taxa were placed in subsection *Holophylla*, a large and very heterogeneous group of species. Walpers (1844) followed Don's system, but elevated Don's subsections to the rank of section. He retained the separation of the taxa based on leaf morphology and kept them in the groups where Don had placed them. In the *Prodromus* (1852) Dunal attempted a worldwide revision of all known species of *Solanum* – the last time this has been so done. In this work he radically re-organized his system of classification, creating an explicit hierarchical structure. Here, Dunal separated pinnate and simple-leaved species of section *Pteroidea*, putting the former in the group *Polybotryon* in subsection *Dulcamara* and the latter in the group *Bassovioides* in subsection *Micranthes* (see Table 2). He described no new species of either group, but included *S. pteleifolium* Sendtn. (as *S. pteleafolium*, see species treatment of *S. mite*) with the pinnate taxa and a group of little-known ambiguous simple-leaved species in the group *Bassovioides* (*S. cormanthum* Vell., *S. laurinum* Dunal, *S. lacteum* Vell., see Excluded Taxa for correct identification and placement of these taxa).

Table 2 Classification of the species of section *Pteroidea* in Dunal (1852).

Sectio I. *Pachystemonum*

Subsectio III. *Dulcamara*. – Cymis terminalibus, dein lateralibus alaribus axillarisque; corollis 5-angulato-plicatis, 5-fidis, 5-partitivis, coeruleis vel albis; baccis globosis ovatisque.

** *Polybotryon*. – Foliis impari-pinnatisectis, segmentis, integerrimis, saepius acuminatis vel simplicibus indivisis; cymis subaxillaris, pluribus, aggregatis vel solitariis, nonnunquam radicibus oppositis; corollis 5-fidis vel 5-partitis.

Subsectio IV. *Micranthes*. – Frutices suffruticosae; foliis integris, glabris, pilosis, tomentosis vel hispidis; calyce 5-fido, 1–2 lin. diam.; corollâ duplo triplo calyce longiore; baccâ globosâ ovatâque, cerasi vel olivae parvae magnitudine.

§ 3. *Bassovioides*. – Cymis subaxillaris intrafoliaceis aut suboppositifoliis; foliis brevioribus 2, 3, 4 aggregatis vel subsolitariis.

The first taxonomist to recognize the close relationship between simple and pinnate-leaved taxa of what is now section *Pteroidea* was Georg Bitter (1912). In describing section *Polybotryon*, he clearly separated the taxa included in Dunal's 'Artengruppe *Polybotryon*' into those with axillary inflorescences and those with leaf-opposed or lateral inflorescences. Bitter explicitly grouped the pinnate and simple-leaved taxa together in his new section *Polybotryon*, stating that the axillary inflorescence was the grouping character. In the section he included *S. conicum*, *S. mite*, *S. trizygum*, *S. fraxinellum*, *S. quinquefoliolatum*, *S. chamaepolybotryon*, *S. diffusum*, *S. ternatum*, *S. pteleifolium*, *S. conjungens*, *S. hederiradiculum*, *S. angustialatum*, and *S. theobromophyllum*, most of which he described in the same paper. In 1921, Bitter united all of Dunal's (1852) various ambiguous grades (excluding the species he recognized as the segregate genus *Lycianthes*) possessing axillary inflorescences and elevated the group to subgeneric rank, as subgenus *Bassovia* (Aubl.) Bitter. He based its elevation in rank solely on the peculiar axillary inflorescence possessed by all species in the group.

Subsequent authors have for the most part followed Bitter in placing these species in a group of subgeneric rank diagnosed by possession of an axillary inflorescence (Seithe, 1962; Danert, 1967, 1970; Gilli, 1970; D'Arcy, 1972; D'Arcy, 1991). No attempts have been made to determine relationships with other groups of solanums. D'Arcy (1991) however, did include section *Pteroidea* as part of subgenus *Solanum* in his review of taxonomy of the Solanaceae. Child (1991) is the only author to place the section in subgenus *Potatoe* (G. Don) D'Arcy, but he did not explain clearly his reasons for doing so. From his introduction, it seems to be largely due to the herbaceous habit of many members of section *Pteroidea*, and perhaps due to their pinnate leaves. Recent cpDNA analyses of the Solanaceae (Olmstead & Palmer, 1991; Spooner et al., 1993) have not included members of section *Pteroidea*, thus it is still largely perceived as an isolated and morphologically very distinct group.

MORPHOLOGY AND NATURAL HISTORY

Species in section *Pteroidea* are all forest understory plants. Members of the group range from being herbs or semi-woody shrubs to 3 m to woody climbers up to 10 m in length. They occur in a wide range of elevations, but always in the deep shade of the forest understory (see Fig. 1a, b). Occasionally some species (e.g. *S. mite*) are found growing along roadsides or streams. *Solanum anceps* occurs at low elevations (at or near sea level) in the Amazon basin and *S. incurvum* to 3000 m in the Peruvian and Ecuadorian Andes. Most species are relatively rare in the habitats in which they occur, but some species (e.g. *S. chamaepolybotryon*) form what appear to be clonal groups.

Stems

Members of section *Pteroidea* are usually slender, single-stemmed shrubs (Fig. 2a) or herbs or are variously climbing. *Solanum mite* has occasionally been described on labels as a branching shrub, but this is not the common growth form for any species in the section. Most of the species will root along the stem; plants of *S. conicum* are apparently weak-stemmed, often falling over and rooting in that fashion. Other species in the group (e.g. *S. uleanum*) are trunk climbers, adhering to the substrate with small, adventitious roots (see Fig. 2b). The two species that we segregate as the *S. ternatum* species group (*S. ternatum*, *S. incurvum*) are quite woody climbers with lower stems up to 3 cm in diameter in some plants. Amongst the species of the *S. mite* species group, woodiness

is only very weakly developed in *S. mite*. Plants range from quite small (a few centimetres in *S. conicum* and *S. chamaepolybotryon*) to more than a metre in height (e.g. *S. savannense*, *S. mite*) to several metres long for some of the vining taxa.

In all *Solanum* species the young non-reproductive stem is monopodial with the leaves arranged in a 2/5 phyllotactic spiral. When a stem begins its reproductive phase, sympodial growth begins (Danert, 1958; Bell & Dines, 1995). Each inflorescence is terminal and shoot continuation is initiated in the axil of the leaf subtending the inflorescence. A single lateral continuation of the shoot produces a monochasial growth pattern, a double one a dichasial pattern. In some species these two patterns occur in a single plant (Bell & Dines, 1995). Bell & Dines (1995) arrange species within the family along a continuum from monochasial to dichasial branching. The determining factor for pattern expression is dormancy of axillary buds in any given sympodial unit. Sympodial units in *Solanum* consist of leaves along each shoot terminating in an inflorescence. In the genus these units can vary from plurifoliate (members of section *Brevantherum*, section *Holophylla*, the *S. nitidum* species group, see Knapp, 1989) to unifoliate (section *Geminata*, see Knapp, 1986a). All members of section *Pteroidea* have what appear to be unifoliate sympodial units (see Fig. 3 for our working hypothesis of stem structure in the group). Danert (1967) was unsure whether the vegetative axis in section *Pteroidea* was monopodial or monochasial (as in the rest of *Solanum*), and urged further ontogenetic studies. Whether or not the unifoliate sympodia of section *Pteroidea* and those found elsewhere in the genus are homologous can really only be determined by such detailed ontogenetic studies.

Leaves

The leaves of members of section *Pteroidea* are generally petiolate (the petiole can be very short or absent in some species, most notably *Solanum angustialatum*), with pinnate, brochidromous venation, and entire margins. Leaf shape has been used widely in section *Pteroidea* for determining relationships (see p. 32). The compound leaves have usually been described as imparipinnate, but are more strictly pinnatifid or deeply pinnately lobed, as thin wings of leaf tissue remain along the midrib or rachis. For the purposes of this treatment, these leaves will be referred to as pinnate, and the divisions will be described as leaflets. The petiole-like constriction at the base of the leaflets will be described as a petiolule. There are seven pinnate and three simple-leaved species in this section. The simple-leaved species, *S. incurvum*, *S. angustialatum*, and *S. anceps*, have entire margins; and in *S. anceps* leaf size, and to some extent leaf shape, is highly variable. Pinnate leaves are generally ternate to 9-jugate, with the terminal leaflet larger, and usually of a somewhat different shape than the paired leaflets. Leaflet numbers vary considerably within and between taxa, and exact numbers of leaflet pairs are generally not good distinguishing characteristics of species, although general trends to more or fewer leaflet pairs are good characters. Leaflet pairs are often not perfectly opposite and are occasionally markedly oblique at the base (e.g. *S. conicum*).

The leaves of members of section *Pteroidea* are often very dark green, a common trait in understory plants. Several species (e.g. *Solanum anceps*, *S. savannense*, *S. uleanum*) develop deep purple leaf undersides in certain conditions. Populations are often highly polymorphic for this character, differing in plants growing side by side. Whether this is due to genetics or environment is unclear. Leaf texture is membranous, as is usually the case in forest understory plants, but the leaves of some species (e.g. *S. chamaepolybotryon*, *S. ternatum*) are quite rubbery in texture, often drying quite thick on

Fig. 1 a) Lowland forest habitat of *S. anceps*, *S. mite*, *S. conicum*, *S. uleanum*: Río Palcazu valley, Pasco, Peru, b) Cloud forest habitat of *S. trizygum*: Cerro Pando, Chiriquí, Panama.

Fig. 2 a) Herbaceous shrub habit of *S. conicum* (Knapp & Mallet 6456, Cusco, Peru), b) Climbing habit of *S. ulicanum* (Knapp & Mallet 6524, San Martín, Peru).

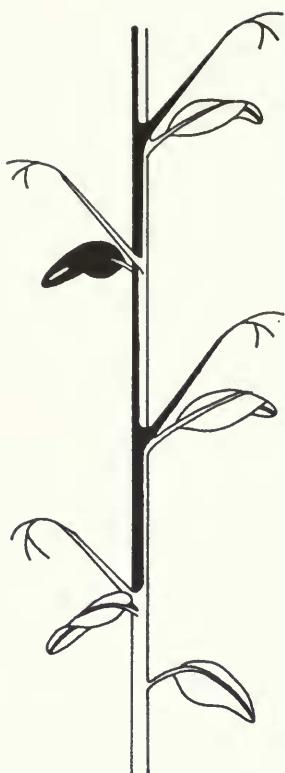

Fig. 3 Sympodial structure in *Solanum* section *Pteroidea* (modified from Danert, 1967).

herbarium sheets. *Solanum uleanum* has very thin and delicate leaves, particularly the juvenile plants.

Plants in the family Solanaceae are widely known for their toxic qualities derived from a diverse array of alkaloids, steroids, and phenolic glycosides (see Brown, 1987 for a review). Herbivorous insects found on the leaves of these plants are often restricted to the family, and many host-specific relationships have evolved. Among the most specialized herbivores on leaves of Solanaceae are the caterpillars of ithomiine butterflies (Nymphalidae: Ithomiinae). The adults of these butterflies are aposematic (Brown, 1987) and have evolved a wide array of colour patterns along the eastern slopes of the Andes. Host specificity of ithomiine larvae is common at species level in *Solanum* (Drummond & Brown, 1987). Very few host

records exist for members of section *Pteroidea*, perhaps due to their understory habitat, or to their small size. The only larvae reared (see Table 3) from members of section *Pteroidea* are species of *Oleria*, a diverse group along the eastern Andean slope. Larvae of *Oleria* feed on a wide variety of other solanums (and on the genus *Lycianthes*) so they are probably not specific to members of the section. Their oviposition behaviour is unusual in that most host-specific lepidoptera oviposit directly on the host plant itself. This behaviour may account for the paucity of records. The senior author has observed *Oleria* females (in Ecuador) testing plants of *S. anceps*, then ovipositing on a stick or another non-solanaceous plant some metres away. This may be a form of parasitoid avoidance behaviour, but detailed ecological field studies need to be carried out.

Inflorescences

The inflorescence of members of section *Pteroidea* is a scorpioid cyme with the flowers arranged in two rows along the axis. This inflorescence type is common to most species of *Solanum* and has been variously misinterpreted as a raceme by earlier authors (Dunal, 1852). The position of the inflorescence is probably morphologically terminal (see p. 33), but due to shoot and inflorescence rachis confluence and subsequent shortening of internodes (Danert, 1967) it is apparently axillary (Fig. 3). The growth of renewal shoots from axillary buds below the inflorescence causes axillary inflorescences in *Cyphomandra* (Bohs, 1994), but the situation in section *Pteroidea* needs detailed anatomical study to ascertain whether the axillary inflorescence is homologous in these two groups. In several species of section *Pteroidea* multiple cymes appear to emerge from each leaf axil. This has been attributed to insertion of a subsidiary shoot on the pleiochasic inflorescence some distance from other subsidiary inflorescences (Child, 1979), but no detailed anatomical work has been done to verify this. The nature of the inflorescence in section *Pteroidea* has been largely responsible for its problematic phylogenetic position and its separation as an isolated subgenus by previous authors (see above).

Inflorescence length is taken from the base to apex, including both the peduncle (length from base to first pedicel) and the rachis (the axis bearing pedicels). Generally in section *Pteroidea* the flowers occur only in the distal half to one third of the usually unbranched inflorescence. The pedicels are articulated at the base, never leaving pegs or prominent scars (see Anderson, 1977; Hawkes, 1990; Bohs, 1994). In any given inflorescence only a few, usually up to three, flowers will be open at a time, but the number of flowers per inflorescence can be determined by counting the number of pedicel scars or remnants. Pubescence of the inflorescence generally parallels that of the rest of the plant and hair types in the inflorescence do not differ from those found on leaves and stems.

Trichomes

Trichomes have traditionally provided many useful characters in *Solanum* taxonomy (Seithe, 1962; Roe, 1971; Seithe, 1979; Edmonds, 1982; Seithe & Anderson, 1982; Whalen, 1984; Knapp, 1991a). In section *Pteroidea*, however, the trichomes of all species are simple, uni- or multicellular, and uniseriate. Thus they have not been particularly useful taxonomic characters in the group. Both *S. anceps* and *S. mite* have variable degrees of pubescence, from densely pubescent to completely glabrous. When analysed as separate taxa during cladistic analysis, however, the pubescent and glabrous plants always are grouped as sister taxa, suggesting that pubescence is polymorphic, as in other groups of *Solanum* (Knapp, 1989). Whether degree of pubescence is developmental or genetic is not known in section *Pteroidea*, but in some groups of spiny solanums

Table 3 Ithomiine larval records from members of *Solanum* section *Pteroidea*.

Butterfly	Host plant	Country	Reference
<i>Oleria vicina</i> (Salvin)	<i>S. trizygum</i>	Costa Rica	Drummond & Brown, 1989
<i>Oleria makrena</i> (Hewitson)	<i>S. trizygum</i>	Venezuela	Drummond & Brown, 1989
<i>Oleria agarista</i> (Felder)	<i>Solanum</i> sp. section <i>Pteroidea</i>	Ecuador	Drummond & Brown, 1989
<i>Oleria janarilla</i> (Hewitson)	<i>S. anceps</i>	Peru	Drummond & Brown, 1989 (based on S.K. record)
<i>Oleria agarista agarista</i> (Felder)	<i>S. mite</i>	Ecuador	Beccaloni, 1995
<i>Oleria agarista agarista</i> (Felder)	<i>S. anceps</i>	Ecuador	Beccaloni, 1995
<i>Oleria</i> sp.	<i>S. anceps</i>	Ecuador	S.K. pers. obs.

(see Whalen et al., 1981; pers. obs. in Ecuador by Leo Roth of *S. marginatum*) lack of prickles is a single gene trait. The juvenile foliage and young leaves and shoots of most of the variably pubescent taxa are much more densely pubescent than mature leaves. *Solanum ternatum* has densely pubescent juvenile foliage (see Fig. 11, Knapp & Mallet 6626) but mature specimens are nearly always glabrate suggesting a developmental aspect to pubescence density. Plants described as *S. dendrophilum* (here treated as a synonym of *S. ternatum*) have dense pubescence more reminiscent of juvenile leaves than other mature individuals of *S. ternatum*.

Flowers

All species have actinomorphic, pentamerous flowers. The calyx is synsepalous and the corolla is sympetalous, although the floral tube is usually very short. The calyx lobes are usually much smaller than the corolla lobes and vary from broadly deltate to almost subulate in some collections of *Solanum anceps*. Pubescence of floral parts parallels that of the rest of the plant, but corolla lobes are generally glabrous except along the tips and margins. There are basically two types of corollas in section *Pteroidea*. In the *S. ternatum* species group the corolla is quite large (12–20 mm in diameter) and fleshy with the apices of the lobes usually planar at anthesis and somewhat cucullate (Fig. 4a). In the *S. mite* species group the corolla is much smaller, usually 5–10 mm (occasionally to 13 mm in *S. conicum*), with more membranous lobes that are usually strongly reflexed at anthesis (see Figs 4, 5). The corolla in both groups can be either white or pale pinkish purple, but many more collections record pigmented flowers in the *S. ternatum* species group than in the *S. mite* species group. All species have five yellow stamens of equal length inserted at the base of the corolla. The filament bases occasionally form a minute tube, but we are unconvinced of its value as a taxonomic character as emphasized by previous authors (Barboza & Hunziker, 1991). Considerable variation exists as to length or even presence of the tube, and its size is variable enough within species to not warrant its use as a taxonomic character. Anthers in members of the *S. mite* species group are shorter and stouter in relation to the corolla lobes than those of the *S. ternatum* species group. Anthers are poricidal at the tips (as in all solanums, e.g. Barboza & Hunziker, 1991) and the pore lengthens to a slit with age (see Barboza & Hunziker, 1991; Endress, 1996). Flowers of *Solanum* species are usually 'buzz-pollinated' by bees (vibratile pollination) (Buchmann, 1983; Knapp 1986a, b; Bohs, 1994). One of us (S.K.) has seen meliponine bees (probably the genus *Melipona*) visiting the flowers of *S. uleanum* in San Martín, Peru, but flower visitors to other species have not been observed or recorded in the literature. The conical ovary is bilocular with axile placentation and there are from few (*S. savannense*) to many ovules (*S. ternatum*). The style is straight, glabrous, papillose to densely pubescent, and usually is exserted from the anther cone. In some species however (*S. conicum*, *S. mite*, *S. anceps*) short-styled flowers do occur in most inflorescences (see Fig. 4). Whether this is indicative of a derived andromonoecious breeding system (Whalen & Costich, 1986; Knapp et al., in press) is not known. The stigma on long-styled flowers is generally small and capitate, and in live plants often bright green. Stigmas of short-styled flowers are poorly developed, as is common in other species of *Solanum* (see Whalen & Costich, 1986). Pollen grains of members of section *Pteroidea* are tricolporate with a granular exine as are all other members of the genus *Solanum* (Anderson, 1977; Punt & Monna-Brands, 1980; Bohs, 1994).

Fruits

Fruits of members of section *Pteroidea* are unusual in *Solanum*.

Fruits in *Solanum* are generally smooth globose berries, but in section *Pteroidea* they are globose to pointed apically and smooth to markedly rugose or warty (see Fig. 5). A few other isolated species of *Solanum* have variously conic berries (*S. capsiciforme* (Domin) G.T.S. Baylis, *S. nigricans* M. Martens & Galeotti, *S. aligerum* Schldl., members of section *Petota* series *Conicibaccata* Bitter, and some members of section *Cyphomandra*), but none of them has the markedly rugose surface found in the berries of section *Pteroidea*. Pointed berries in section *Pteroidea* are of two kinds: conic, where the apex is full of seeds, and apiculate, where the apex is empty of seeds and is prolonged into an occasionally elongate beak. *Solanum trizygum*, *S. chamaepolybotryon*, *S. savannense*, and *S. conicum* all have conic fruits. *Solanum uleanum*, this group's closest relative, has a round fruit with a truncate apex empty of seeds that is conspicuously membranous and flattened in dried specimens. In the other species, the fruits are basically globose to ovoid, and often apiculate, varying from slightly apiculate in immature berries of *S. mite* to long-pointed in *S. anceps*. In *S. anceps*, variants in fruit shape are geographically coherent, suggesting that there may be discrete morphological clusters within the species as currently delimited. All fruits within section *Pteroidea* are green, and held erect in most species. An exception to this is *S. mite*, where fruits are nodding at maturity. Fruits and seeds provide many of the best characters for distinguishing species in this group. The identification of non-fruiting specimens of some taxa is difficult, and collectors are urged to record fruit characteristics in field notes.

Nothing is known about the fruit or seed dispersal in *Solanum* section *Pteroidea*. All species produce green fruits that remain green at maturity, although mature fruits are quite soft and juicy. *Solanum trizygum* fruits (observed by S.K. in Monteverde, Costa Rica) apparently fall to the forest floor rather than being taken by birds or bats as is so common in other *Solanum* species. It is possible that they are eaten and thus dispersed by small ground-dwelling rodents. Fruits of the herbaceous species may be too close to the ground to be taken by bats, but those of the climbing species may be dispersed by bats. Mature fruits of *S. trizygum* smell strongly of wintergreen, but this has not been observed or noted by collectors for any other species in the section.

Seeds

The seeds of members of section *Pteroidea* are typical for *Solanum* and essentially reniform in outline. They differ however from the more typical solanum seed in being plump and somewhat ellipsoid (ovoid-reniform) rather than flattened. As in most of the studied species of *Solanum* the lateral epidermal cell walls are thickened and lignified (Souèges, 1907; Lester & Durrants, 1984; Edmonds, 1983; Bohs, 1994). Seed colour is not uniform in section *Pteroidea*. Seeds of the species in the *S. mite* species group tend towards greenish brown, whereas the *S. ternatum* species group has reddish to orange-brown seeds. Seed colours have been coded as they appear in dried specimens, but in the case of the three or four taxa that have only one specimen with mature seed, this should be treated with some caution. Seed colour is an inconsistent character in the phylogenetic analysis (see p. 43) and is occasionally dependent on whether or not the specimen has been air-dried, dried over very hot driers or preserved in alcohol before drying.

The fine structure of seeds has been useful for resolving the relationships among species where morphological characters exhibit complex patterns of variation. In Solanaceae, lateral cell wall structure can be seen after enzymatic digestion of the outer cell wall (Lester & Durrants, 1984). In order to examine cell wall structures, seeds were collected from herbarium specimens (BM, F, GH, MO,

NY) and washed in a 20% v/v solution of sodium hypochlorite. They were then incubated in a 1% w/v solution of Driselase (SIGMA) in Sorensen's buffer at pH 5.5 for 24 hrs at 30°C. Prepared seeds were washed in distilled water, air dried, and mounted on aluminium stubs using epoxy resin. These were then coated in a Gold-Palladium mixture, and photographed using a Hitachi S-2500 scanning electron microscope.

The most striking feature of the seed structures revealed by enzymatic digestion is the absence in eight of the ten taxa of projections from the cell wall thickenings (Fig. 7). Of the few species of *Solanum* that have been treated, to our knowledge, in this way, none have been found within the genus that have the combination of thickened walls without projections (see e.g. Edmonds, 1983; Knapp, 1991a). Two species have projections from the thickened walls, *S. incurvum* (hair-like, Fig. 6a) and *S. ternatum* (flap-like, Fig. 6b), both species with larger flowers. There also appears to be variation among the species in cell size, though this would have to be confirmed using additional samples. In *S. anceps*, *S. mite*, and *S. trizygum* (the only species for which samples were available from more than one specimen) cell size, shape, and structure is consistent within a species and over a wide geographic range. The other striking character of the seed coat is the highly convoluted cell shape in most taxa (Fig. 7). This may be unusual even within the family, where most specimens analysed have cells that have a more or less regular shape, even where the cell walls are sinuous, e.g. *S. ternatum* (Fig. 6c). Seed coat characters shown in the SEM study are congruent with other seed and fruit characters, and provide many of the supporting characters for the two species group clades revealed by the cladistic analysis (see p. 43). It cannot be said with certainty, however, whether these are plesiomorphic or a synapomorphic characters without a more comprehensive investigation of this character throughout the genus.

CLADISTICS

Few explicit morphologically based cladistic treatments for groups of *Solanum* exist. Increased interest in the use of molecular characters has meant an increase in the use of parsimony analyses, but to date only a few groups of solanums have been studied (Knapp, 1989, 1991b; Spooner et al., 1993). In part the difficulty in attempting character analyses in *Solanum* lies in its extreme diversity and in the choice of appropriate outgroups. Choosing a range of outgroups (Watrous & Wheeler, 1981) has been thought to increase the likelihood of obtaining an accurately rooted tree. Recent work, however (Nixon & Carpenter, 1993), has shown that multiple outgroups perform no better at 'polarizing' ingroup nodes, but that multiple outgroups might improve inference.

Character coding and tree construction

Most of the characters used in the analysis are binary, and were polarized with reference to the outgroup, the *S. nudum* species group (see below). Most characters are self-explanatory but details on the variation and distribution of morphological characteristics in the species of section *Pteroidea* can be found in the section on morphology. Table 4 lists the characters used and their states and the data matrix is presented in Table 5.

The cladistic analyses were undertaken using the computer programme HENNIG86 (Farris, 1988) using the *ie** option (implicit enumeration) with all characters unordered. The ensemble consistency index (CI) is a measure of consistency in the entire data set with respect to the fit of characters to the tree. When the fit of a character

is perfect (with no parallelisms or reversals) then the consistency index is 1. The ensemble retention index (RI) is the fraction of apparent synapomorphy in all characters retained as synapomorphies on the tree (Farris, 1989). The *Solanum nudum* species group (section *Geminata*) was selected as the outgroup as its species are of somewhat generalized morphology and are thought to be basal among non-spiny solanums (Bohs, pers. comm.; Knapp, 1989, 1991b). *Cyphomandra* was initially also used, but produced very low resolution in the tree, especially with unordered characters. This reflects the difficulty in classifying *Cyphomandra* and perhaps its problematic position in the genus *Solanum* (Bohs, 1994; also see below).

The analysis produced three most parsimonious trees of length = 55 steps, CI = 0.52 and RI = 0.52, one of which has exactly the same topology as the strict consensus tree (Fig. 8). The other two tree topologies differed in the placement of *Solanum mite* relative to the rest of the *mite* clade: in the first *S. mite* was basal to the clade (*mite* + [*chamaepolybotryon* + the rest]), while in the second *S. mite* and

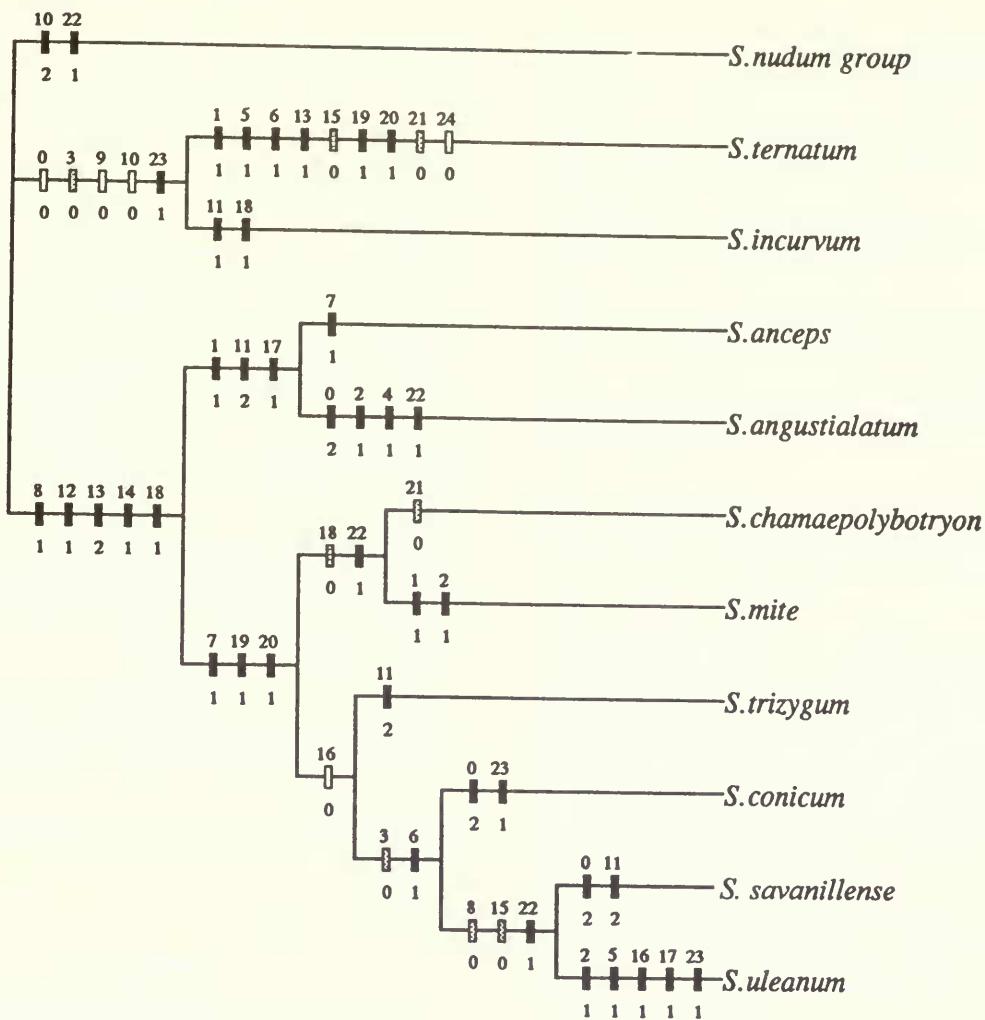

Fig. 8 Cladogram of *Solanum* section *Pteroidea*. L = 55, CI = 0.52, RI = 0.52. For characters marked on the branches of the cladogram: unshaded marks indicate synapomorphies, stippled marks indicate reversals and parallelisms (homoplasy), and solid marks non-homoplastic synapomorphies.

S. chamaepolybotryon were sister to the rest of the clade ([*mite* + *chamaepolybotryon*] + [the rest]). Analysis of the changes in each character suggest strongly that these tree topologies are largely defined by the suite of seed characters (see Fig. 8), with the exception of seed colour. These characters separate the *ternatum*-*incurvum* clade, whose members have small 'hairy' seeds and many seeded fruits, from the *S. mite* species group, whose members have ovoid-reniform seeds without projections and fewer seeds per fruit. This shows clearly that pinnate leaves are a derived character of the group, and that it has arisen twice, once in the *S. mite* species group, and once in *S. ternatum*. The simple-leaved taxa do not form a separate clade. These trees provide clear support for the treatment of section *Pteroidea* as two distinct monophyletic species groups (see Table 6), and we suggest that in any treatments of the genus *Solanum* at a group level, these clades should be treated as separate monophyletic groups. Section *Pteroidea* as a whole is clearly not a monophyletic group (see p. 32) and although treated as a unit for the purposes of this monograph, should not be lumped in further cladistic analyses. It may be that other taxa, if included in the analysis, would be placed as sister groups to either of these clades – a possibility hinted at by the very low resolution of the tree when *S. diploconos* (Mart.) Bohs (as *Cyphomandra*) was used as an outgroup, and confirmed by the fact that when added to the matrix presented here, it was the sister taxon to *S. ternatum*, with *S. incurvum* basal to the clade.

Classification

We prefer not to assign ranks or formal names to the groups found in these analyses until further cladistic studies are done more widely in the genus *Solanum*. The monophyletic clades identified here, however, have been given informal species group names (following the convention of Whalen, 1984) and their classification is summarized in Table 6. Groups of equal 'rank' are indented equally and the sequencing convention (Nelson, 1974; Forey, 1992) has been used.

TAXONOMIC TREATMENT

Solanum section *Pteroidea* Dunal, *Hist. nat. Solanum*: 43 (1813).
Lectotype species: *Solanum mite* Ruiz & Pav. (D'Arcy, 1972).

Bassovia Aubl., *Hist. pl. Guiane* 1: 217, t. 5 (1775). Lectotype species: *Solanum sylvaticum* (Aubl.) Bitter [basionym *Bassovia sylvatica* Aubl.] (= *Solanum anceps* Ruiz & Pav.) (D'Arcy, 1972).

Solanum grad. ambig. *Polybotryon* Dunal in DC., *Prodr.* 13(1): 28, 66 (1852), pro parte. Lectotype species: *Solanum mite* Ruiz & Pav. (D'Arcy, 1972).

Solanum section *Polybotryon* Bitter in *Reiprium nov. Spec. Regni veg.* 11: 469 (1912). Lectotype species: *Solanum mite* Ruiz & Pav. (D'Arcy, 1972).

Solanum subgenus *Bassovia* (Aubl.) Bitter in *Reiprium nov. Spec. Regni veg.* 17: 329 (1920/1?). Lectotype species: *Solanum sylvaticum* (Aubl.) Bitter [basionym *Bassovia sylvatica* Aubl.] (= *Solanum anceps* Ruiz & Pav.) (Bitter, 1921).

Slender wand-like shrubs, herbs or woody high-climbing lianas; young stems and leaves pubescent or glabrous, the trichomes if present simple and uniseriate. Leaves simple or pinnate (pinnatisect), fleshy or membranous, often very dark green in live plants, leaf undersides often dark purple or reddish. Inflorescence a scorpioid cyme borne in the axil of the leaf, unbranched, usually bearing 5–30 flowers; pedicel scars not raised. Buds usually rounded to ellipsoid, strongly exserted from the minute calyx tube. Flowers sympetalous, stellate, the tube very short; corolla 5–20 mm in diameter, fleshy or membranous, in the *S. ternatum* species group the lobes planar at anthesis and usually cucullate, in the *S. mite* species group the lobes usually reflexed at anthesis, sometimes strongly so; stamens five, the anthers poricidal at the tips, with age splitting longitudinally, bright yellow. Fruit a berry, usually green or yellowish green when mature, globose with a smooth surface (*S. incurvum*, *S. ternatum*, *S. mite*) or variously conical with a rugose surface; fruiting pedicel nodding or erect. Seeds flattened-reniform, many per fruit (*S. ternatum*, *S. incurvum*) or ovoid-reniform and few per fruit.

Section *Pteroidea*, as here delimited, consists of ten species in two monophyletic clades (see p. 43). The clades are both kept in the section (s.l.) at this time for convenience, despite some doubt as to their degree of relatedness. The *S. ternatum* clade, consisting of *S. incurvum* and *S. ternatum*, has large, lilac or pinkish flowers and globose fruits with many, small, flattened seeds, while the larger *S. mite* clade, consisting of *S. anceps*, *S. angustialatum*, *S. chamaepolybotryon*, *S. conicum*, *S. mite*, *S. savanillense*, *S. trizygum*, and *S. uleanum*, has smaller, usually greenish flowers, and (with the exception of *S. mite*) conical fruits with unusual rugose surfaces, the fruits having a few, ovoid, often bright green, seeds. These rugose fruits are unique in *Solanum*. The section has been accorded subgeneric status by many previous authors (Bitter, 1921; Seithe, 1962; Danert, 1967; D'Arcy, 1972, 1991), on the basis of its extreme morphological difference from the rest of *Solanum*. We feel, however, that until phylogenetic relationships in *Solanum* are much more clearly resolved, the group (as two clades) should be recognized only at the sectional level.

This monograph is based on herbarium specimens and the extensive field observations of the senior author. The species are delimited on morphological grounds, with geographical and ecological preferences being taken into account where appropriate. More than half of the published names of this species group have as a result, been

placed in synonymy. Most of these are synonyms of the two most widely distributed species, *S. mite* and *S. anceps*. *Solanum mite* is relatively homogeneous (excluding variation in pubescence) over its range, whereas *S. anceps* has a number of forms that are somewhat geographically coherent. This variation is described in the species account. Section *Pteroidea* is a poorly collected group, and the material on which many of these descriptions are based is somewhat limited.

A general comment here on the lectotypification, particularly of Ruiz & Pavón names, will save repetition in the species accounts. We have lectotypified all of these names using specimens from MA matched, if possible, to plates in *Flora peruviana et chilensis* (Ruiz & Pavón, 1799). In most cases the choice was straightforward, but when not, we have chosen the best specimen. Other lectotypes have been chosen with an eye to the wide distribution of isolectotypes. When this was not possible, the best preserved specimen was selected. Any lectotype not directly attributed to another author is designated by us here.

Photographs of type specimens are cited in the recommended manner (see Knapp, 1989, 1991a), with the negative number cited in square brackets. Herbaria in possession of prints of that negative are also included in the brackets. Copies of these negatives are generally available from the institutions where they are housed: F for F negatives and US for Morton negatives.

Herbaria are cited using the acronyms in *Index herbariorum* (Holmgren et al., 1990) and types seen are indicated by an exclamation mark (!). All non-type specimens cited in the species accounts have been seen by the authors, unless otherwise indicated.

|---|--|----------------------------|
| 1 | Leaves simple | 2 |
| | Leaves variously pinnate | 4 |
| 2 | Climbing herbs; flowers 1.2–1.4 cm in diameter, purplish; fruit globose, the surface smooth; seeds many per fruit (>50) | 1. <i>S. incurvum</i> |
| | Terrestrial herbs or weak subshrubs; flowers 0.4–0.7 cm in diameter, white or greenish white; fruit ovoid, beaked, the surface rugose; seeds few per fruit (usually 10–40) | 3 |
| 3 | Stem prominently winged; style densely pubescent along its entire length. San Martín, Peru | 4. <i>S. angustialatum</i> |

- Stem smooth, terete, not winged; style glabrous or at most papillate in the lower 2/3. Widespread 3. *S. anceps*
- 4 Climbing herbs or woody vines 5
- Terrestrial herbs or wand-like subshrubs, occasionally in large colonies
- 6 Woody vines, the basal stems often to several cm in diameter; flowers 1.6–2 cm in diameter, the petals planar, fleshy, cucullate; fruit globose, the surface smooth. 2. *S. ternatum*
- Herbaceous vines; flowers 0.6–1 cm in diameter, the petals strongly reflexed, not fleshy or markedly cucullate; fruit conical, the surface rugose. 10. *S. uleanum*
- 6 Leaves with 5 or fewer leaflets, the leaflets usually obovate, especially the terminal 7
- Leaves usually with more than 5 pairs of leaflets, the lateral leaflets lanceolate to elliptic, the terminal leaflet similar in shape, not markedly obovate 10
- 7 Leaves pubescent on the veins and lamina on both surfaces 8
- Leaves glabrous on lamina, occasionally pubescent along the veins and rachis 9
- 8 Fruit conical; leaf pubescence denser adaxially 8. *S. savanillense*
- Fruit globose, smooth; leaves equally pubescent on both surfaces. 7. *S. mite*
- 9 Fruit conical, the surface rugose; leaves fleshy; plants very small and rooting along the stem 5. *S. chamaepolybotryon*
- Fruit globose or at most apically pointed, the surface smooth; leaves membranous; plants often woody at the base and up to 1 m tall 8. *S. mite*
- 10 Flowers 5–6 mm in diameter, the petals strongly reflexed at anthesis; fruit globose, smooth 8. *S. mite*
- Flowers 9–13 mm in diameter, the petals usually planar or only slightly reflexed at anthesis; fruit conical, rugose 11
- 11 Flowers > 10 mm in diameter; leaflets long-petiolulate, the petiolule 3–17 mm; leaves densely pubescent in a groove along the adaxial side of the rachis 6. *S. conicum*
- Flowers < 10 mm in diameter; leaflets short-petiolulate, the petiolule c. 1 mm long; leaves only sparsely pubescent if at all and then only with a few scattered trichomes abaxially 9. *S. trizygum*

The *Solanum ternatum* species group

1. *Solanum incurvum* Ruiz & Pav., *Fl. peruv.* 2: 34, fig. 154b (1799). Type: Peru, Huánuco, Muña, August, September, Ruiz & Pavón s.n. (MA!-lectotype [F neg. 29716, F!]).

Fig. 9.

Climbing herb, up to 2 m in length at maturity, often trailing along the forest floor. *Stems* c. 8 mm in diameter, minutely to densely pubescent with simple uniseriate trichomes 0.3–1.0 mm long. *Leaves* simple, 6–20 × 3–9 cm, elliptic to ovate, with c. (5)6–7 pairs of primary veins, glabrous to somewhat densely pubescent with simple uniseriate trichomes, denser along the veins both abaxially and adaxially, the base acuminate, the apex acute; petiole 1.5–9 cm long, glabrous to pubescent with simple uniseriate trichomes, glabrate. *Inflorescence* to 12 cm long, axillary, 1–3 inflorescences per leaf axil, bearing 3–6 open flowers at a time, with up to 12 scars, glabrous to sparsely pubescent with simple uniseriate trichomes. *Buds* rounded, becoming ellipsoid, strongly exserted from the calyx tube. *Pedicels* at anthesis 0.8–1.8 cm long, 1–2 mm in diameter, quite soft and lax,

pendent, glabrous to sparsely pubescent like the rest of the inflorescence. *Flowers* with the calyx tube c. 0.5 mm long, conical, the sides very straight, the lobes 1–2 × 1–2 mm, acute to slightly obtuse and spreading, glabrous to sparsely pubescent with a few scattered uniseriate trichomes; corolla 12–14 mm in diameter, reddish violet to purple, the tube c. 2 mm long, the lobes 5–6 mm long, planar to very slightly reflexed, sparsely pubescent abaxially, the tips minutely papillate; anthers 3–4 × 1–1.2 mm; free portion of the filaments minute, the filament tube minute; ovary globose to bottle-shaped, glabrous; style c. 6 mm long, straight, glabrous; stigma minutely capitate. *Fruit* a globose (somewhat conical when immature) berry, 1–1.3 × 1–1.3 cm, green at maturity, drying black, the surface smooth; fruiting pedicel 1–1.5 cm long, nodding. *Seeds* c. 80–100 per fruit, 1–2 mm, flattened-reniform, orange-brown; epidermal cells regular, rectangular, with long hair-like projections, especially at the margins.

COMMON NAMES AND USES. None recorded.

DISTRIBUTION. Eastern slopes of the Andes from S. Ecuador to S. Peru, montane forest and forest edges, 1540–3000 m. (Fig. 10).

SPECIMENS EXAMINED

ECUADOR. Morona-Santiago: 9–10 km SE of San Juan Bosco, 1540–1600 m, 27 January 1981, Gentry et al. 30871 (MO).

PERU. Huancavelica: Chojimacota Valley, Huanta, 2800–2900 m, 28 February 1926, Weberbauer 7570 (F, MOL). Huánuco: Playapampa, 2750 m, 16 June 1923, Macbride 4491 (F). Pasco: Oxapampa, trail to summit of Cordillera Yanachaga via Río San Daniel, 3000 m, 75°27'W, 10°23'S, 13 July 1984, Smith 7756 (MO, USM); Oxapampa. Río San Alberto valley E. of Oxapampa, 2700 m, 75°22'W, 10°27'S, 26 July 1984, Smith & Poetel 8069 (MO). San Martín: Valley of Río Apisoncho, 30 km above Jucusbamba, 2800 m, 77°10'W, 7°55'S, 6 August 1965, Hamilton & Holligan 1069 (K).

Solanum incurvum is one of the most poorly collected species in section *Pteroidea*. It grows at the highest elevations, and is apparently not at all common where it occurs. Considerable variation in pubescence exists among the few specimens examined, which apparently is not correlated with elevation or any other discernible ecological factor. Like its close relative, *S. ternatum*, it is reported to have lilac flowers, but variation for flower colour may exist.

2. *Solanum ternatum* Ruiz & Pav., *Fl. peruv.* 2: 38, fig. 162b (1799). Type: Peru, Huánuco, Cuchero, June, July, Ruiz & Pavón s.n. (MA!-holotype; B, destroyed [F neg. 2639, F!, MO], F!-isotypes).

Figs 4a, 11.

- Solanum diffusum* Ruiz & Pav., *Fl. peruv.* 2: 37, fig. 161b (1799).

Type: Peru, Huánuco, sin loc., June, July, August, Ruiz & Pavón s.n. (MA!-holotype, fragment F!). F neg. 12996 is of an obvious isotype of *Solanum diffusum*, but some confusion exists as to the labelling: prints with negative number 12296 (F!, MO!, NY!) are said to have been taken at B, but photographs without a negative number of the same sheet (F!, GH!, US!) are said to have been taken at MA.

- Solanum semievectum* Bitter in *Reptium nov. Spec. Regni veg.* 11: 542 (1913). Type: Peru, sin loc., Poeppig s.n. (B-holotype, destroyed [F neg. 2638 – F!]).

- Solanum moritzianum* Bitter in *Reptium nov. Spec. Regni veg.* 11: 565 (1913). Type: ‘Nouvelle Grenade’, either Venezuela or Colombia, sin loc., December 1852, Moritz 1028 (P-lectotype [F neg. 39192, G!, US!]; BM!, HBG!, K!, P [Morton neg. 8357, F!, GH!, US!]).

- Solanum feddei* Bitter in *Reptium nov. Spec. Regni veg.* 12: 67

Fig. 9 *S. incurvum*. Habit: Gentry et al. 30871 (MO). Inflorescence: Hamilton & Holligan 1069 (K).

(1913). Type: Peru, Huánuco, Muña, May 1863, Pearce s.n. (K!-holotype).

Solanum dendrophilum Bitter in *Reptum nov. Spec. Regni veg.* 12: 143 (1913). Type: Peru, San Martín, Cerro Campana, Spruce 4385 (K!-holotype; K!-isotype).

Solanum semiscandens Bitter in *Reptum nov. Spec. Regni veg.* 12: 142 (1913). Type: Peru, Huánuco, Muña, 10–11000 ft, May 1863, Pearce s.n. (K!-holotype).

Solanum subquinatum Bitter in *Reptum nov. Spec. Regni veg.* 12: 144 (1913). Type: Peru, Amazonas, Chachapoyas, 1835, Matthews s.n. (BM!-lectotype; K!-isolectotype).

Solanum diffusum subsp. *miozygum* Bitter in *Bot. Jb.* 54: (Beibl. 119); 14 (1916). Type: Peru, Pasco, valley of Río Pozuzo, tributary of Río Palcazu, 9°46'–9°50'S, 2200 m, 1909–1914, Weberbauer 6783 (B-holotype, destroyed; MOL!-lectotype; F!-isolectotype).

Solanum diffusum var. *miozygum* (Bitter) J.F. Macbr. in *Publ. Field Mus. (Bot.)* 8: 111 (1930). Basionym: *Solanum diffusum* subsp. *miozygum* Bitter.

Woody, high climbing vine, to 6–7 m (or more) long. Stems c. 0.5 cm in diameter, quite stout and woody at the base and somewhat four-

Fig. 10 Distribution of *S. incurvum*.

lobed, greenish, not conspicuously white-lenticellate, glabrous to sparsely to densely (type of *S. dendrophilum*) pubescent with simple, uniseriate trichomes 2–3 mm long, these drying white and cateniforme. Leaves pinnate, 9–15 × 8–12 cm, ternate or with 2–4 pairs of leaflets, somewhat fleshy, pubescent with scattered to dense simple uniseriate trichomes along the veins abaxially, glabrous to densely pubescent adaxially, the trichomes 5–10-celled, c. 2–3 mm long; petiole 2–6 cm long; lateral leaflets 2–6 × 1–3 cm, lanceolate or narrowly elliptic to elliptic or obovate, if the leaf more than ternate the leaflets usually narrower, with 4–6 pairs of primary veins, the base attenuate, oblique, enlarged basiscopically, the apex acute; petiolule 0.5–1 cm; basal leaflets smaller than the laterals if the leaf more than ternate; terminal leaflet 2–10 × 1–3 cm, slightly more obovate, the base attenuate, the apex acute to occasionally acuminate; petiolule c. 0.5 cm. Inflorescence axillary, 1.5–6 cm long, bearing flowers only in the distal 1/3, simple, occasionally 2 per axil, with 2–4 flowers open at a time, the pedicel scars raised, widely spaced, up to 24 per inflorescence. Buds elliptic, c. 6 × 3 mm, strongly exserted from the calyx tube. Pedicels at anthesis 1–1.3 cm long, c. 0.5 mm in diameter, erect to horizontal. Flowers with the calyx tube very open, almost flat, c. 2 mm long, the lobes 1.5–2 × 2 mm, quadrate with a distinct apical lobe, glabrous to sparsely pubescent with simple uniseriate trichomes like the rest of the plant; corolla 16–20 mm in diameter, white to greenish to pink, lobed c. 3/4 of the way to the base, the lobes cucullate, planar at anthesis,

minutely papillate at the tips and along the margins; anthers 4–5 × c. 2 mm, slightly sagittate at the base, poricidal at the tips; free portion of the filaments c. 0.5 mm long, the filament tube absent; ovary conical, glabrous; style c. 8 mm long, glabrous; stigma capitate to clavate. Fruit a globose to slightly apically pointed, green berry, 1–1.2 cm in diameter, 1–1.5 cm long, the surface smooth; fruiting pedicel 1.5–1.7 cm long, fleshy, c. 2 mm in diameter at the apex, pendent. Seeds 80–140 per berry, 1.2–2 × 1.2–1.8 mm, flattened, almost round, reddish brown; epidermal cells more or less regular, with flap-like thickenings.

COMMON NAMES AND USES. None recorded.

DISTRIBUTION. Tropical wet forest to humid cloud forest, in deep shade or forest edges from 100–2800 m. In the Andean region from Colombia and Venezuela to Bolivia. (Fig. 12).

Solanum ternatum can be a very large woody liana, with lower stems up to 2 cm in diameter. In cross-section these woody stems are in the shape of an '8'. Like many of the members of the section, considerable variation in pubescence exists within the species, with densely pubescent specimens having been described as *S. dendrophilum*. The degree of fleshiness of the leaves of *S. ternatum* has also led to the description of many synonyms, but this character is unrelated to geography or habitat, and seems to vary at random throughout the range of the species. Polymorphism in flower colour is common throughout the species range, and unlike members of the *S. mite* species group, purple flower colour does not co-occur with purple leaf undersides (see *S. anceps* and *S. savanillense*).

The *Solanum mite* species group

3. *Solanum anceps* Ruiz & Pav., *Fl. peruv.* 2: 36, fig. 149a (1799).

Type: Peru, Huánuco, Cuchero, July, August, *Ruiz & Pavón* s.n. (MA!-holotype [F neg. 29722, F!, GH!, MO!, US!]).

Figs 5c, 13.

Bassovia sylvatica Aubl., *Hist. pl. Guiane* 1: 217, fig. 75 (1775).

Type: French Guiana, Aublet s.n. (BM!-lectotype).

Solanum bassovia Dunal in Poir., *Encycl. suppl.* 3: 754 (1814);

Solan. syn.: 22 (1816). nom. nov. for *Bassovia sylvatica* Aublet.

Solanum aubletii Pulle, *Enum. vasc. pl. Surinam*: 411, fig. 16 (1906). nom. nov. for *Bassovia sylvatica* Aubl.

Solanum conjungens Bitter in *Reprimum nov. Spec. Regni veg.* 11: 12 (1912). Type: Ecuador, Tungaragua, prope Baños, September 1892, *Sodiro* 114/61 (B-holotype, destroyed [F neg. 2656, F!, G!, GH!, MO!, NY!]; possible lectotype to be found in the Sodiro herbarium in Ecuador which is held privately in the monastery where he was resident).

Solanum hederiradiculum Bitter in *Reprimum nov. Spec. Regni veg.* 11: 12 (1912). Type: Peru, Loreto, Yurimaguas, August 1902, *Ule* 6276 (B-holotype, destroyed [F neg. 2608, F!, G!, GH!, MO!, US!]; HBG!-lectotype).

Solanum theobromophyllum Bitter in *Reprimum nov. Spec. Regni veg.* 11: 472 (1912). Type: Brazil, Amazonas, Rio Juruá, Cachoeira Miry, May 1901, *Ule* 5490 (W!-holotype; G!, HBG!-isotypes).

Solanum theobromophyllum var. *procerius* Bitter in *Reprimum nov. Spec. Regni veg.* 12: 145 (1913). Type: Brazil, Acre, Estella, 1912, *Ule* s.n. (no herbarium cited). Bitter cited no herbarium when he described this variety, and specifically cited the date of the collection as 1912. However, a Ule collection (at G!, K!) labelled 'Rio Acre, Seringal Auristella, E. Ule 9735' could be type material. The sheet at G is dated March 1911 and the K sheet is dated April 1911. In the 1913 publication, Bitter cited many K collections, but the K sheet is only annotated '*Solanum theobromophyllum*' in Bitter's hand and dated 1914. The location of the type of this variety remains obscure.

Solanum sylvaticum (Aubl.) Bitter in *Reprimum nov. Spec. Regni veg.* 17: 330 (1921). non *Solanum sylvaticum* Dunal, *Solan. syn.*: 24. (1816). (= *Lycianthes sylvatica* (Dunal) Bitter, a synonym of *Lycianthes geminata* (Vahl) Bitter).

Slender, single-stemmed shrub, to 2 m tall. Stems c. 4 mm in diameter, green, conspicuously white-lenticellate, glabrous to minutely red-papillate on new growth to densely pubescent with simple uniseriate trichomes c. 0.5 mm long. Leaves simple, 12–45

× (3–)5–15 cm, very variable in size, elliptic to obovate, with 10–15 pairs of primary veins, glabrous to densely pubescent with simple uniseriate trichomes c. 0.5–1 mm long, these soon deciduous on the lamina and remaining only sparsely along the veins, the base acute to attenuate (truncate in isolated populations near Iquitos), the apex acute to acuminate; petiole 1–5 cm long. Inflorescence axillary, 1–3 cm long, c. 2–4 per axil, simple, bearing flowers c. 1 cm from the base, with 3–4 flowers open at a time, c. 40–60 pedicel scars, glabrous or if the plant pubescent then with scattered uniseriate trichomes. Buds globose, c. 2 mm in diameter, c. 1/2 included in the calyx tube. Pedicels at anthesis 5–7 mm long, c. 0.5 mm in diameter, nodding. Flowers with the calyx tube c. 1 mm long, broadly conical, the lobes broadly deltate, 0.5–1 × 1–1.5 mm, glabrous or sparsely pubescent with uniseriate trichomes; corolla white, 5–7 mm in diameter, lobed nearly to the base, the lobes reflexed at anthesis, densely papillose at the tips and along the margins; anthers 1.5–2 × c. 1 mm, poricidal at the tips, free portion of the filaments c. 0.05 mm, the filament tube c. 0.05 mm; ovary conical, glabrous; style 4–5 mm long, minutely papillate in lower 2/3 or glabrous; stigma clavate. Fruit a conical, green berry, 1–1.2 cm in diameter, 1–2.3 cm long, the beak 2–8 mm, occasionally breaking off and appearing absent, the surface rugose, the raised portions white; fruiting pedicel 0.8–1.8 cm long, erect. Seeds 2–3.5 × 1.5–2.2 mm, greenish brown, flattened, round to ovoid-reniform, c. 40 seeds per fruit; epidermal cells highly sinuous and irregular, with anticlinal thickenings but without projections.

COMMON NAMES AND USES. Peru: 'ullcu panga' (Williams 7322).

DISTRIBUTION. Colombia to Bolivia and into Brazil, from 100–nearly 3000 m, in a wide range of wet forest habitats. (Fig. 14).

Solanum anceps is one of the most widespread and variable of the species of section *Pteroidea*. It is basically an Amazonian lowland species, but is found in the Andes in Peru and Bolivia up to elevations of about 2000 m. There is little discernible difference between the high elevation and low elevation forms of *S. anceps* as so often occurs in other groups of *Solanum* (see Knapp, 1986a, 1991a). Considerable geographical variation in pubescence exists within *S. anceps*, with some densely hairy populations being found throughout the species range. New leaves are always more densely pubescent than mature leaves and there may be a developmental or genetic component to pubescence in *S. anceps*. Leaf size also varies a great deal in *S. anceps*, with some leaves attaining very large sizes in shady habitats. Purple leaf undersides are common in *S. anceps* and are noted on many herbarium labels. Unlike in *S. savannense*, the purple colour of leaves is not also found in flowers (see discussion of *S. savannense*). The senior author has seen plants with and without purple leaves growing side by side, so perhaps there is a genetic rather than environmental cause for this characteristic.

In lowland Peru (departments of Loreto & Ucayali), a series of specimens appear quite distinct. These plants (given a manuscript name honouring A.C. Smith by C.V. Morton) have longer petioles, more truncate leaf bases, and somewhat more pointed fruits, but a series of well-marked intermediates occur and thus we prefer to retain this variant within *S. anceps*. Some specimens from Bolivia have more strongly decurrent leaf bases than those from farther north, but again, a complete range of intermediates exist. The degree to which these forms are reproductively isolated and may be in the process of speciation or differentiation is worth further study. Other characters, such as DNA sequence or leaf chemistry, may differ in concert with the morphological ones observed here.

4. *Solanum angustialatum* Bitter in *Reprintum nov. Spec. Regni veg.* 11: 471 (1912). Type: Peru, San Martín, near Tarapoto, Spruce 4849 (W!-holotype [F neg. 33045, F!, MO!, US!]; BR!, G!, K!-isotypes).

Figs 4b, 5d, 13.

Small single-stemmed shrub or herb, to c. 1 m tall. Stems c. 5 mm in diameter, completely glabrous, green or purple, conspicuously white-lenticellate, conspicuously winged, the wing c. 4 mm wide and often purple, the internodes usually short. Leaves simple, 13–35 × 4–15 cm, elliptic, with 18–20 pairs of primary veins, completely glabrous, occasionally purple abaxially, the base narrowing c. 1–3 cm from the stem to a winged petiole, the apex acuminate, occasionally abruptly; petiole 1–3 cm, strongly winged, the wings continuing onto the stem. Inflorescence axillary, 1–3 cm long, occasionally 2 per axil, simple, with c. 2–3 flowers at a time, c. 30 pedicel scars, minutely papillate. Buds globose, 1.5–2 mm in diameter, exserted from the calyx tube. Pedicels at anthesis 7–8 mm long, c. 0.5 mm in diameter, horizontal with a marked kink, so the flowers are nodding. Flowers with the calyx tube 0.5–1 mm long, broadly conical, the lobes c. 0.5 × 1 mm, broadly deltate to rounded, glabrous; corolla white, 4–5 mm in diameter, lobed nearly 3/4 of the way to the base, nodding at anthesis, the lobes very strongly reflexed at anthesis, densely papillate on both surfaces; anthers c. 2 × 1.5 mm, poricidal at the tips, free

portion of the filaments less than 0.05 mm, the filament tube absent; ovary conical, densely red-papillose; style 2–3 mm long, densely white-pubescent with white papillae c. 0.05 mm long along its entire length; stigma clavate, often markedly bifid. *Fruit* a conical, green berry, c. 1 cm in diameter, 1.5–2 cm long, the beak 2–4 mm long, the surface rugose, the raised portions white; fruiting pedicel 7–8 mm long, erect, enlarged at the apex. *Seeds* 2–3.5 × 1.5–2.2 mm, greenish brown, flattened-round to ovoid-reniform, c. 20 seeds per fruit; epidermal cells highly sinuous and irregular, with anticlinal thickenings but without projections.

COMMON NAMES AND USES. None recorded.

DISTRIBUTION. Middle elevation premontane forests in NE Peru, 700–1200 m, only known from the Maynesian Andes (see Spruce, 1908). (Fig. 14).

SPECIMENS EXAMINED

PERU. San Martín: Trail to television antenna, Cerro de la Escalera, km 17.5 of Tarapoto-Yurimaguas road (2.5 km N. of Cataratas de Ahuashiyacu), 850–1200 m, 7°21'W, 6°27'S, 7 September 1986, Knapp 8277 (MO, USM); Cataratas de Ahuashiyacu, km 15 Tarapoto-Yurimaguas road, 700 m, 7°21'W, 6°29'S, 19 August 1986, Knapp & Alcorn 7792 (MO, USM); trail to television antenna, Cerro de La Escalera, km 17.5 of Tarapoto-Yurimaguas road (2.5 km N. of Cataratas de Ahuashiyacu), 850–1200 m, 7°21'W, 6°27'S, 7 August 1986, Knapp 7905 (F, MO, NY, USM); trail to television antenna, Cerro de La Escalera, km 17.5 of Tarapoto-Yurimaguas road (2.5 km N. of Cataratas de Ahuashiyacu), 1200 m, 7°21'W, 6°27'S, 24 January 1987, Knapp & Mallet 8567 (K, MO, NY, US, USM).

Solanum angustialatum is only known from the area above Tarapoto (Departamento San Martín, Peru) in wet premontane forest. It is sympatric with *S. anceps* and is perhaps derived from that species. The eastern slopes of the Andes are an area of very high diversity, with many species of extremely local distribution. The type of *S. angustialatum* was collected by Spruce in what he called the Maynesian Andes (Spruce, 1908), an isolated chain running between approximately Pucallpa (Ucayali) and Bagua on the Río Marañón (Departamento Amazonas). Many of the plants collected by Spruce were only known from their types until recent collecting in the area of Tarapoto and the mountains behind it (S.K. in 1986) added substantially to holdings of these plants. Further collecting in other parts of this small but quite distinct mountain range may reveal range extensions for many of these apparent narrow endemics.

The broadly winged stem of *S. angustialatum* is sometimes difficult to see on herbarium specimens, but the strongly decurrent leaves are quite distinctive and unlike those occurring in *S. anceps*.

5. *Solanum chamaepolybotryon* Bitter in *Reprint nov. Spec. Regni veg.* 11: 471 (1912). Type: Peru, San Martín, prope Tarapoto, 1855–56, Spruce 4432 (W!-holotype [F neg. 33057, F!, G!, MO!, US!]; K!-isotype).

Small fleshy *herb*, 10–30 cm tall. Stems slender, glabrous or with a few simple uniseriate trichomes in a distinct line along one side, not conspicuously lenticellate, green or purplish. Leaves pinnate, c. 20 × 10 cm, elliptic to obovate, with c. 2 pairs of leaflets, glabrous or pubescent with simple uniseriate trichomes c. 0.5 mm long, along the veins, rachis and petiole; petiole c. 3 cm long; lateral leaflets 3.5–7 × 1–2.5 cm, with c. 5 pairs of primary veins, the base attenuate, the apex acute to acuminate; petiolule c. 0.5 cm, lightly winged; basal leaflets equal to the laterals in size and shape; terminal leaflet more obovate, 4.5–8.5 × 1–2.5 cm, the base long-attenuate onto the rachis, the apex acuminate; petiolule 0.5–1 cm long, often winged and not differentiated from the rachis. Inflorescence axillary, 0.5–1 cm long, simple, bearing flowers only at the tip, with c. 2 flowers open at a time, c. 5

scars, glabrous. *Buds* globose, c. 1 mm in diameter, exserted from the calyx tube. *Pedicels* at anthesis 3–5 mm long, filiform, horizontal or nodding. *Flowers* with the calyx tube conical, 0.5–1 mm long, the lobes 0.5–1 × 0.5–1 mm, deltate, glabrous or with a few scattered simple, uniseriate trichomes; corolla greenish yellow or purple, 7–8 mm in diameter, lobed nearly to the base, the lobes reflexed (?) at anthesis, minutely papillate at the tips and along the margins; anthers c. 1.5 × 0.5 mm, poricidal at the tips, the free portion of the filaments c. 0.5 mm long, the filament tube c. 0.5 mm long; ovary conical, glabrous; style 2–2.5 mm long, glabrous; stigma minutely capitate. *Fruit* (immature) a conical, green berry, c. 4 mm in diameter, c. 1 cm long, the beak c. 3 mm long, surface unknown, but appearing somewhat rugose; fruiting pedicel c. 1 cm long, erect. *Seeds* not seen.

COMMON NAMES AND USES. None recorded.

DISTRIBUTION. In N. Peru in the Maynensian Andes of Spruce (Spruce, 1908). (Fig. 15).

SPECIMENS EXAMINED

PERU. San Martín: Rioja, near km 398 of Carretera Marginal between Pomacochas & Rioja, trail to Quebrada Venceremos and Río Serranoyacu, 1300–1400 m, 10 July 1984, Knapp & Mallet 6590 (BH, K, US, USM).

Solanum chamaepolybotryon is the most diminutive species of the *S. mite* species group and apparently only grows as a small, fleshy herb in middle elevation cloud forest in NE Peru. It has only been collected a few times, but is apparently clonal and grows in large groups (Knapp & Mallet 6590). This species also occurs in the Maynesian Andes of Spruce (1908, see discussion under *S. angustialatum*) and may be derived from the more widespread *S. mite* or *S. conicum*.

6. *Solanum conicum* Ruiz & Pav., *Fl. peruv.* 2: 88, fig. 162b (1799).

Type: Peru, Huánuco, Chinchao et Cuchero, August, September, Ruiz & Pavón s.n. (MA!-lectotype; B [F neg 2602, F!, G!, GH!, MO!, NY!] destroyed, F!-isolectotypes).

Figs 2a, 16.

Solanum alatibaccatum Bitter in *Reprint nov. Spec. Regni veg.* 12: 68 (1913). Type: Ecuador, Loja, Palandra, 22 October 1906, André s.n. (K!-holotype).

Erect or climbing (scrambling) *herb*, to 2 m in length (height). Stems c. 0.5 cm in diameter, glabrous, greenish, conspicuously white-lenticellate when dry. Leaves (10–)15–25(–38) × (6–)12–17(–20) cm, pinnate, elliptic, with (3–)4–5(–9) pairs of leaflets, often unevenly paired and not perfectly opposite, glabrous abaxially, densely pubescent adaxially along the midribs of the leaflets and extending to the rachis, a few scattered trichomes on the lamina, the trichomes c. 0.25 mm long, simple, uniseriate, composed of 5–6 cells, drying white; petiole 2–9 cm long; rachis densely pubescent adaxially in a groove with simple uniseriate trichomes c. 0.25 mm long; lateral leaflets 6–12 × 1–2.8 cm, lanceolate to narrowly elliptic, with 8–9 pairs of veins, the base truncate, somewhat oblique, the apex long-acuminate, petiolule 0.3–1.5 cm; basal pair of leaflets markedly smaller than the laterals, 1.5–6 × 0.7–2 cm, lanceolate to narrowly elliptic, the base truncate, oblique, the apex long acuminate, petiolule 0.3–1.7 cm; terminal leaflet 7–12 × 1.2–3 cm, elliptic, the base truncate to acute and somewhat decurrent onto the rachis, the apex long acuminate, petiolule 0.3–1.5 cm long. Inflorescence 0.7–2.5 cm long, simple or occasionally once-branched, with 3–6 flowers open at a time, with c. 10–16 scars, finely and densely pubescent with simple uniseriate trichomes less than 0.25 mm long or with whitish papillae. *Buds* c. 0.5 mm in diameter, globose to obovate, exserted from the calyx tube. *Pedicel* at anthesis 0.5–0.8 cm long, c.

Fig. 15 Distribution of *S. chamaepolybotryon* (star in circle) and *S. conicum* (circles).

0.5 mm in diameter, nodding, finely pubescent like the rest of the inflorescence. Flowers with the calyx tube 0.5–1 mm long, conical, the lobes 0.5–1 × c. 0.5 mm, broadly deltate to triangular with an apical projection, papillate to finely pubescent like the rest of the inflorescence; corolla 10–13 mm in diameter, greenish white to white, lobed nearly to the base, the lobes more or less reflexed at anthesis, densely papillate at the tips and margins; anthers c. 2 × 1.5 mm, poricidal at the tips, free portion of the filaments 1–1.5 mm long, the filament tube absent; ovary conical, glabrous; style c. 5 mm long, glabrous; stigma minutely capitate. Fruit a long-conical, sharply pointed, green berry, 1.5–1.8 × c. 1 cm, the surface rugose, the rugosities white; fruiting pedicel 0.8–1 cm long, horizontal or nodding. Seeds c. 2.0 × 2.0 mm, flattened-round, brown, c. 40 seeds per fruit; epidermal cells sinuous and irregular, with anticlinal thickenings but without projections.

COMMON NAMES AND USES. Ecuador: ‘palu rugu’ (*Shemlück* 303 – stems and leaves as a tea for snakebite).

DISTRIBUTION. Premontane and montane forests, 200–2000 m, S. Ecuador to SE Peru. (Fig. 15).

Fig. 16 *S. conicum*. Habit: Smith 4170 (NY) and Knapp & Mallet 6456 (K). Fruit: Smith 4170 (NY).

Solanum conicum is superficially very similar to *S. mite* in the vegetative state. Differences include the larger numbers of lanceolate to elliptic (rather than obovate) leaflets with long petiolules, its habit of becoming scandent and rooting along the stem, and its very conical fruit with a pointed apex and rugose surface texture. Leaflets are more elliptic than those of either *S. uleanum* or *S. mite*, and generally have strongly oblique, somewhat truncate bases. *Solanum conicum* can be confused with larger leaved specimens of *S. uleanum*, but the leaflets are not so decurrent on the rachis nor so rounded looking as those of the latter. In southern Peru *S. conicum* more closely resembles *S. mite* than in other parts of its range and non-fruiting specimens are hard to tell apart. Like most of the other species in section *Pteroidea* great variation in pubescence occurs throughout the species range, with some very densely specimens occurring in all areas.

7. *Solanum mite* Ruiz & Pav., *Fl. peruv.* 2: 38, fig. 163a (1799).
Type: Peru, Junín, Pozuzo et Chinchao, August, September, Ruiz & Pavón s.n. (MA!-lectotype; B-isolectotype [F neg. 2625-F!]).
Figs 5a, 17.

Solanum pteleifolium Sendtn. in Mart., *Fl. bras.* 10: 15 (1846).
Type: Brazil, Amazonas, trajectu Puraque-Goara, R. Negro, June–October, Martius s.n. (M!-lectotype [F neg. 6538 – F!, NY!, US!]; M!-isolectotypes). The original spelling *pteleaefolium* is correctable under Article 60.8 of the *Code* (Greuter et al., 1994) to *pteleifolium*.

Solanum mite subsp. *hexazygum* Bitter in *Regium nov Spec. Regni veg.* 11: 10 (1912). Type: Bolivia, La Paz, San Carlos bei Mapiri, 15°S, 700 m, August 1909, Buchtien 1438 (US!-lectotype; NY!-isotype). Bitter cited two herbaria in his original description – Herb. Buchtein, now housed at US and Herb. Vratisl. (either WRSL or BRA, both of which Bitter could have visited) from which we have not been able to obtain a specimen.

Solanum quinquefoliolatum Bitter in *Regium nov. Spec. Regni veg.* 11: 11 (1912). Type: Brazil, Amazonas, Marary, Rio Juruá, Ule 5201 (B-syntype, destroyed; G!-lectotype [F neg. 23148, F!, MO!, NY!, US!]).

Solanum huallagense Bitter in *Regium nov. Spec. Regni veg.* 12: 138 (1913). Type: Peru, Loreto, Yurimaguas, Río Huallaga, May 1885, Spruce 3882 (K!-lectotype; BM!, BR!, W! [F neg. 33079, G!, MO!, US!] isolectotypes). In the original description of this species, Bitter cites specimens at K, BM, and W. The sheet at K, selected here at the lectotype, is from the first set of Spruce's collections and is annotated in Bitter's hand.

Solanum apiculatibaccatum Bitter in *Regium nov. Spec. Regni veg.* 12: 141 (1913). Type: Brazil, Acre, Cobija, January 1912, Ule 9731 (No herbarium cited by Bitter, but F neg. 2705 [F!, G!, GH!] is of a sheet at B that is now no longer extant which may perhaps have been the type).

Small single-stemmed shrub to 1 m tall, often growing in large colonies in open places. Stems c. 1 cm in diameter, green, white-lenticellate, very woody at the base, when dry usually hollow, extremely variable in pubescence, from glabrous to densely pubescent with simple uniseriate trichomes 1–1.5 mm long, these drying white and cateniforme. Leaves pinnate, 10–50 × 7–25 cm, elliptic to obovate, with 2–5 pairs of leaflets, the leaflets not always perfectly opposite, the pubescence reflecting that of the entire plant, glabrous to densely pubescent both adaxially and abaxially with simple uniseriate trichomes on the veins and the lamina, the trichomes 1–2 mm long, white, leaves glabrescent with age, but not markedly so, leaves rarely purple abaxially; petiole 5–15 cm long; lateral leaflets

elliptic to obovate, 7.5–15 × 2–3 cm, with c. 12–14 pairs of primary veins, the base attenuate, markedly oblique and enlarged basiscopically, the apex acute to acuminate; petiolule 2–3 mm; basal leaflets usually somewhat smaller than the laterals, but similar in shape; terminal leaflet obovate, usually much wider than the laterals, 9–15 × 3.5–8(–10) cm, the base attenuate, usually winged and decurrent onto the rachis, the apex acute to acuminate; petiolule winged onto the rachis. Inflorescence axillary, 0.5–5 cm, 1–8 arising from an axil, occasionally once-branched, bearing 5–10 flowers at anthesis, with up to 100 scars, pubescence as the rest of the plant, glabrous to densely pubescent. Buds globose, c. 2 × 2 mm, exserted from the calyx tube. Pedicels at anthesis 4–6 mm long, filiform, nodding. Flowers with the calyx tube 1–1.5 mm, broadly conical, abruptly narrowing to the pedicel, the lobes 1–1.5 × c. 1 mm, deltate, glabrous to sparsely pubescent with simple uniseriate trichomes like the rest of the inflorescence; corolla 5–6 mm in diameter, greenish white, lobed nearly to the base, the lobes strongly reflexed at anthesis, the tips and margins minutely papillate, occasionally in pubescent plants with a few simple uniseriate trichomes abaxially; anthers 1–1.5 × 1–1.5 mm, poricidal at the tips, papillose abaxially, the free portion of the filaments 0.5–1 mm long, the filament tube 0.05 mm; ovary conical, glabrous; style 3–4 mm long, glabrous or minutely papillose in the lower half, some flowers short-styled and the style included in the anther cone; stigma capitate to slightly clavate. Fruit a globose, occasionally somewhat apically pointed, green berry, 0.8–1.2 cm in diameter, 1–1.2 cm long, the surface smooth; fruiting pedicel 0.8–1 cm long, nodding. Seeds 2.3–3.0 × 1.6–2.3 mm, ovoid-reniform, brown, 35–60 seeds per fruit; epidermal cells sinuous and irregular, with anticinal thickenings but without projections.

COMMON NAMES AND USES. Peru: 'arco sacha blanco' (Martin et al. 1619).

DISTRIBUTION. Throughout the Amazon basin from Colombia and the E. slopes of the Andes in Peru and Bolivia to the mouth of the Amazon in Brazil, from nearly sea level to 1500 m (Fig. 18).

SPECIMENS EXAMINED

COLOMBIA. Putumayo: Selva higrofíla entre Quebrada de la Hormiga y San Antonio de Güamaes, 330 m, 18 December 1940, Cuatrecasas 11151 (US); Río Caqueta, downriver from Puerto Limón, 300–350 m, 20 December 1968, Plowman 2185 (GH).

ECUADOR. Napo: Estación Biológica Jatun Sacha, 450 m, 77°36'W, 1°04'S, 24 August 1988, Cerón & Cerón 4604 (MO, NY, QCNE); Estación Biológica Jatun Sacha, Río Napo, 8 km al E. de Misahualli, 400 m, 77°36'W, 1°04'S, 11–14 April 1989, Cérón 6389 (MO, NY, QCNE); Reserva Faunística Cuyabeno, Río Aguarico, Zancudo detrás del Campamento militar, 230 m, 75°32'W, 0°29'S, 25 September 1991, Palacios et al. 7684 (QCNE); Estación Biológica Jatun Sacha, S. floodplain of Río Napo, 375–400 m, 77°36–37'W, 1°04'S, 30 July 1990, Webster 28483 (QCNE). **Pastaza:** Lotorachi, pica a Lagatococha a 1 hora siguiendo margen derecha del Río Curaray, 200 m, 75°59'W, 1°39'S, 1 June 1980, Jaramillo et al. 31719 (AAU, F, NY). **Zamora-Chinchipe:** Taisha, 1500 ft, 5 February 1962, Cazalet & Pennington 7676 (B); Shaime, at junction of Río Nangarita & Río Numptakai, 100–1080 m, 78°42'W, 4°22'S, 7 December 1990, Ølggaard 98451 (AAU, QCNE).

PERU. Amazonas: Bagua, Cordillera Colan SE of Peca, 7500–7900 ft, 7 October 1978, Barbour 3831 (MO); trail E. from La Peca into Serranía de Bagua, 100–1400 m, 15 June 1978, Gentry et al. 23086 (F, MO); Bongara, c. 7 km above Pedro Ruiz on road to Pomacochas, c. 1500 m, 77°57'W, 5°58'S, 3 July 1984, Knapp & Mallet 6561 (BH, US, USM); 8 km above Pedro Ruiz (Jazan) on road to Pomacochas, 1500–1600 m, 77°53'W, 5°55'S, 3 June 1986, Knapp & Alcorn 7541 (C, MO, USM). **Huánuco:** Tingo María, 625–1100 m, 30 October 1949–19 February 1950, Allard 20481 (F, US); Tingo María, 7 July 1940, Asplund 12043 (US); highway Tingo María-La Oroya, 15.5 km W. of Tingo María, March 1977, Boeke 1200 (NY); at Río Haullaga at Tingo María, 4 October 1972, Croat 21039 (F, GH, MO); on route 16, near km 39

Solanum mite is the most common of the species of section *Pteroidea*, forming large thickets in treefall gaps in the primary and secondary forest and along streams and roads in partial shade. Like *S. anceps*, it is basically an Amazonian species, but unlike *S. anceps*, *S. mite* occurs only in the southern part of the Amazon basin, not extending far north of the N. bank of the Río Amazonas. *Solanum mite* is superficially similar to both *S. conicum* and *S. oleanum*, but can be differentiated easily from those species by its rounded fruit, pendent at maturity. *Solanum mite* can be hard to distinguish from *S. conicum* in flower, but the latter generally has larger flowers with petals held planar at anthesis, while *S. mite* has tiny ones with reflexed petals. Other differences from *S. conicum* are discussed with that species. Numbers of leaflets and size of leaves are extremely variable in *S. mite*, but leaflet shape is consistently obovate, with the terminal leaflet usually much larger and more enlarged in the distal

Fig. 19 *S. savannense*. Habit, flowers, and fruit: Madsen & Elleman 75239, Madsen 85749, 85898 (AAU).

third. The type specimen of *S. pteleifolium* (Martius s.n.) has ternate leaves with very large, broad leaflets. There exists however a range of intermediates in both leaflet numbers and size: Maas et al. P12838 from Acre, Brazil and Plowman et al. 6401 from near Leticia on the Colombia/Peru border approach Martius's collection in their broader leaflets, but given the range of variability in *S. mite*, we prefer to take a broad concept of the species. Many of the minor variants have been described as separate species by Bitter (see synonymy), but the range of variation in *S. mite* as recognized here encompasses all of these.

Huge variability in leaf pubescence of collections made by one of us (S.K.) in Departamento San Martín, Peru, shows that pubescence

density and occurrence is quite variable within populations of *S. mite*. In these collections, made in the Tarapoto area in 1986, no differences in phenology or other ecological characteristics were observed, and no morphological differences other than pubescence were seen. The nature of inheritance of this character is not known, but is likely to be relatively simple.

8. *Solanum savannense* Bitter in *Reptum nov. Spec. Regni veg.* **12: 66 (1912). Type: Ecuador, Zamora-Chinchipe, Tambo de Savanilla, 18 December 1876, André 4565 (K!-holotype). Figs 4d, 5b, 19.**

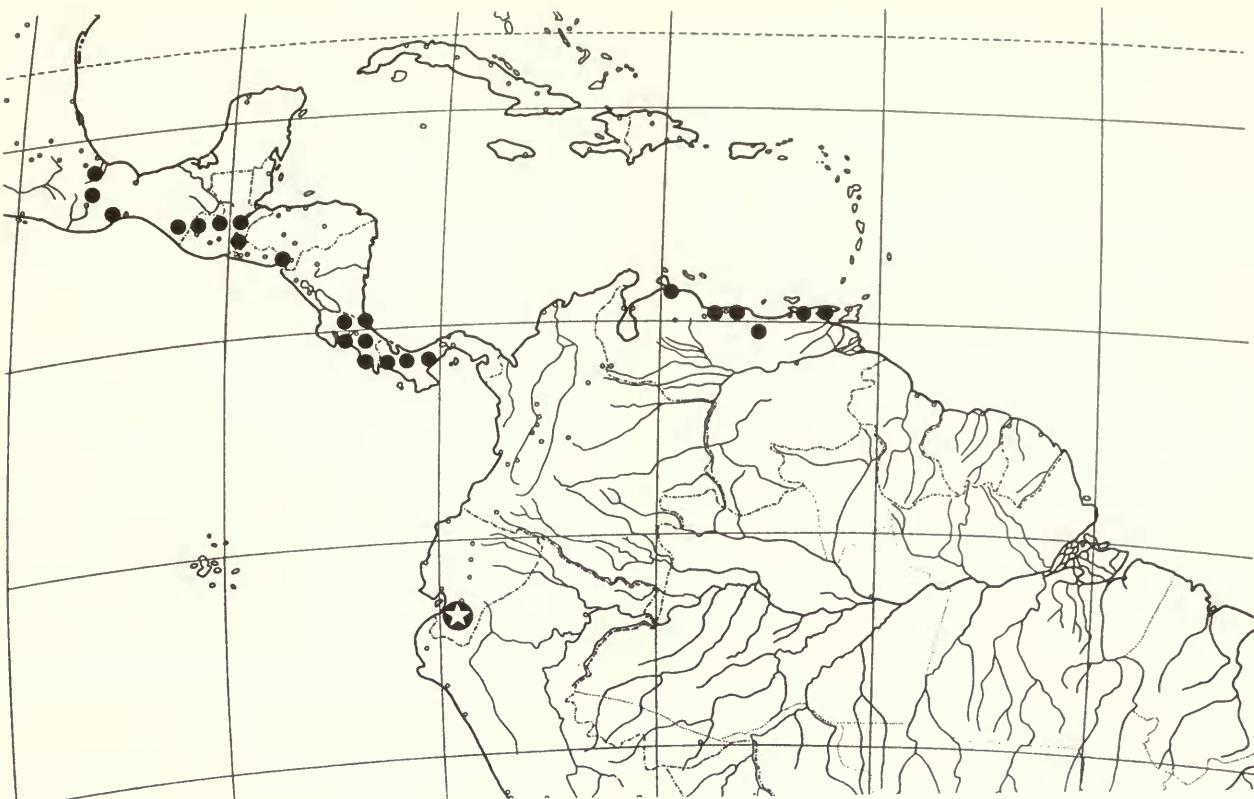

Fig. 20 Distribution of *S. savannense* (star in circle) and *S. trizygum* (circles).

Slender, wand-like shrub to 1.2 m tall. Stems c. 7 mm in diameter, fleshy and somewhat translucent, completely glabrous or with a few scattered uniseriate trichomes near the somewhat swollen nodes, the nodes occasionally dark purple, usually the stems green without conspicuous lenticels when dry. Leaves 10–17 × 7–16 cm, pinnate, with 1–2 pairs of leaflets, occasionally purple abaxially, sparsely pubescent abaxially with simple uniseriate trichomes c. 0.5 mm long, 4–5-celled, these denser along the veins, more densely pubescent adaxially, the trichomes c. 1 mm long and 8–10-celled; petiole 3.5–4 cm long; rachis of leaf minutely winged, sparsely pubescent with simple, uniseriate trichomes c. 0.05 mm long; lateral leaflets obovate, 10–12.5 × 3–5.5 cm, the base attenuate, the apex acuminate; petiolule 0.5–0.8 cm long; basal leaflets obovate, smaller, 5–10.5 × 1.7–4.2 cm, the lamina often narrower on the acroscopic side of the leaflet, the blade attenuate, the apex acuminate; petiolule c. 0.5 cm; terminal leaflet obovate, broader than any of the laterals, 6–16 × 3–7 cm, the base attenuate, the apex acuminate; petiolule c. 1 cm long. Inflorescence 1–3 cm long, simple, up to 3 rachis arising from a single leaf axil, bearing flowers only in the distal half, with only 1 or 2 flowers open at a time, but with c. 10–15 scars, sparsely pubescent with simple, uniseriate trichomes like those of the leaves. Buds c. 0.5 cm in diameter, globose to ovate, strongly exserted from the calyx tube. Pedicels at anthesis 0.5–0.7 cm long, c. 0.5 mm in diameter, nodding, glabrous or minutely pubescent. Flowers with the calyx tube 1.5–2 mm long, conical, the lobes c. 0.5–1 × 0.5 mm, deltate, splitting irregularly at the sinuses, with a prominent terminal projection, sparsely pubescent with trichomes like those of the inflorescence, the trichomes denser on the tip of the lobes; corolla 10–12 mm in diameter, white or purple (see discussion), lobed nearly to the base, the lobes planar at anthesis, densely papillate at the tips and margins; anthers 2.5–3 × c. 1 mm, poricidal at the tips, free portion of the filaments c. 0.5 mm long, the filament tube

minute; ovary conical, glabrous; style 5–6 mm long, densely short-pubescent in the lower half; stigma clavate. Fruit an elongate, conical green berry, 1–2 × c. 1 cm, the surface lightly rugose; fruiting pedicel 1–1.2 cm long, erect. Seeds c. 3.0 × 2.5 mm, ovoid-reniform, bright green, c. 20 per fruit; epidermal cells highly sinuous and irregular, with anticlinal thickenings but without projections.

COMMON NAMES AND USES. None recorded.

DISTRIBUTION. S. Ecuador in cloud forest, from 2300–3000 m. (Fig. 20).

SPECIMENS EXAMINED

ECUADOR. **Loja:** Sin loc., 1876, André K694 (K); Parque Nacional Podocarpus, Nudo de Cajanuma; sendero del Centro de Información a las Lagunas del Compadre, 2830–2880 m, 21 November 1990, Gavilanes et al. 381 (AAU); Parque Nacional Podocarpus, Cajanuma, trail to El Mirador, 2800–3200 m, 4°07'S, 79°10'W, 20 October 1994, Knapp et al. 9044, 9045 (QCNE); Parque Nacional Podocarpus, above Nudo de Cajanuma around Centro de Información, 2800–3000 m, 79°10'W, 4°05'S, 6 September 1988, Madsen & Elleman 75238 (AAU, LOJA); Parque Nacional Podocarpus, above Nudo de Cajanuma around Centro de Información, 2800–3000 m, 79°10'W, 4°05'S, 6 September 1988, Madsen & Elleman 75239 (AAU); Parque Nacional Podocarpus, E. of Nudo de Cajanuma, just N. of Centro de Información, 2900 m, 79°10'W, 4°05'S, 31 January 1989, Madsen 85749 (AAU, LOJA, QCNE); Parque Nacional Podocarpus, above Nudo de Cajanuma around Centro de Información, 2800–3000 m, 79°10'W, 04°05'S, 14 May 1988, Øllgaard et al. 74105 (AAU); Parque Nacional Podocarpus, at Cajanuma, S. of Loja, at Centro de Información, 2900 m, 79°10'W, 4°05'S, 31 May 1988, Øllgaard 74539 (AAU, LOJA); Parque Nacional Podocarpus, E. of Nudo de Cajanuma, trail E. of Centro de Información, to crest on trail to Lagunas de Compadre, 2850–3050 m, 79°10'W, 4°05'S, 7 June 1988, Øllgaard 74630 (AAU, LOJA). **Zamora-Chinchipe:** Pass between Loja and Zamora and along trail toward Zamora, 2360–2800 m, 29 July 1982, Clements et al. 2252 (NY); Parque Nacional Podocarpus, road Loja-Zamora, just E. of pass, 2800 m, 79°07'W, 3°58'S, 15 March 1989, Madsen 85898 (AAU).

Solanum savannense is superficially similar to many of the other pinnate-leaved members of section *Pteroidea*. It can be distinguished easily, however, by its larger flowers, more elliptic, slightly less rugose fruits and its tall stature. This last character is impossible to ascertain from herbarium sheets, but in the field *S. savannense* is quite distinct from *S. mite* or *S. conicum*, the only other members of this group to attain such sizes. The leaves of *S. savannense* are more pubescent adaxially than abaxially, the reverse of the pattern in other members of the group. In 5-foliate leaves of *S. savannense*, the basal pair of leaflets is conspicuously smaller than the other pair, a characteristic not found elsewhere in the section.

In Parque Nacional Podocarpus in southern Ecuador *S. savannense* is polymorphic for both flower and stem colour but the leaves are monomorphic. In populations collected ascending the Nudo de Cajanuma, groups of plants were either green-stemmed and white-flowered or with purple nodes and purple flowers. Leaf undersides of neither morph were purple as occurs in *S. anceps* (see discussion under that species), perhaps indicating that the colour variation in *S. savannense* is purely genetic in origin. *Solanum savannense* grows in the primary forest understory in deep shade.

Bitter, in describing *S. savannense*, stated that the type was collected in Costa Rica. André never collected in Costa Rica, but was in southern Ecuador in December of 1876. The type specimen does not bear any annotation stating Costa Rica, so it is likely that Bitter made a mistake in transcribing label data or just confused the localities of specimens he saw at K. André's locality Tambo de Savanilla probably corresponds to the present-day village of Sabanilla in the province of Zamora-Chinchipe or to the pass on the Loja to Zamora road ($3^{\circ}38'S$, $79^{\circ}05'W$), which lies within the Parque Nacional Podocarpus. In Ecuador, *nudo* means a pass and *tambo* a stopping place, usually a small town.

9. *Solanum trizygum* Bitter in *Regium nov. Spec. Regni veg.* 11: 470 (1912). Type: Venezuela, Distrito Federal, Colonia Tovar, Moritz 1644 (B-holotype, destroyed [F neg. 2702, F!, G!, GH!, MO!, NY!, US!, WIS!], fragment at F!; HBG!-lectotype; BM!, HBG!-isolectotypes). A Moritz collection (BM!, F!, GH!, W [F neg. 33118, F!, MO!, US!, WIS!]) distributed from W could also be type material, but as it is labelled 'Colombia, leg. Moritz' we have excluded it from consideration.

Fig. 21.

Solanum fraxinellum Bitter in *Regium nov. Spec. Regni veg.* 11: 469 (1912). Type: Mexico, Veracruz, prope Mirador, 3000–3800 ft, Sartorius s.n. (W!-holotype [F neg. 33075, F!, G!]; G!-isotype [Morton neg. 8516, F!, GH!, NY!]).

Solanum trizygum var. *tetrazygum* Bitter in *Regium nov. Spec. Regni veg.* 11: 471 (1912). Type: Venezuela, sin loc., 27 June 1891, Eggers 13223 (C!-holotype).

Solanum quinquejugum Bitter in *Regium nov. Spec. Regni veg.* 11: 564 (1912). Type: Mexico, Puebla, Teziutlán, July 1866, Hahn s.n. (P!-holotype [F neg. 39200, G!]).

Solanum pittieri Bitter in *Regium nov. Spec. Regni veg.* 12: 66 (1912). Type: Costa Rica, Heredia, Alto del Roble, 2000 m, 1888, Pittier 18 (G!-holotype).

Somewhat woody shrub to 1 m. Stems c. 5 mm in diameter, usually bright green and fleshy, completely glabrous, but occasionally with sparse reddish papillae (when dry) or simple uniseriate trichomes scattered near the nodes. Leaves $10\text{--}40 \times 5\text{--}10$ cm, pinnate, elliptic, with 3–6 (most commonly 4) pairs of leaflets, glabrous or minutely papillose adaxially, occasionally with a few uniseriate trichomes along the veins abaxially, occasionally purple abaxially and along the rachis; petiole 2–5 cm long; lateral leaflets lanceolate to elliptic,

$4\text{--}15(25) \times 2\text{--}4$ cm, with 6–8 pairs of primary veins, the base attenuate, only very occasionally oblique, the apex acuminate; petiolule 0.1 cm long; basal leaflets either equal to the laterals or somewhat smaller; terminal leaflet similar in shape to the laterals, $6\text{--}20 \times 3\text{--}6$ cm, the base attenuate, the apex acuminate; petiolule c. 1 cm or less. Inflorescence axillary, 1–4(–9) cm long, simple, c. 2–4 arising from a single axil, bearing 2–3 flowers at a time, with 20–30 pedicel scars, glabrous or minutely papillate at the tip. Buds elliptic, the calyx strongly 5-ridged (in dry specimens) in early bud, c. 3×2 mm, strongly exserted from the calyx tube. Pedicels at anthesis 1–1.5 cm, c. 0.5 mm in diameter at the tip, nodding. Flowers with the calyx tube 1–1.5 mm, open-conical, the lobes deltate to broadly triangular, $0.5\text{--}1 \times 0.5\text{--}1$ mm, glabrous; corolla 9–10 mm, greenish white or white, lobed nearly to the base, the lobes reflexed at anthesis, minutely papillose at the margins and tips; anthers 2–2.5 \times 1–1.5 mm, poricidal at the tips, the free portion of the filaments 0.5–1 mm long, the filament tube absent; ovary conical, glabrous; style 5–6 mm long, minutely papillose in the lower half; stigma minutely capitate, occasionally somewhat clavate. Fruit a conical, green berry, the beak not abruptly narrowed, c. 1–1.2 cm in diameter, 1.2–2.5 cm long, the surface rugose, the raised portions white, when ripe smelling distinctly of wintergreen; fruiting pedicels 1.5–2 mm long, c. 3 mm in diameter at the apex, erect. Seeds 3.0 \times 2.0–2.5 mm, ovoid-reniform to elliptic, greenish brown, c. 40 seeds per fruit; epidermal cells sinuous and irregular, with anticlinal thickenings but without projections.

COMMON NAMES AND USES. Guatemala: 'candelaria' (Steyermark 33815, 35135, 37209, 37732, 48735, 51729); Venezuela: 'ajicillo' (Berry 1926).

DISTRIBUTION. Montane and premontane forest from Mexico to the Cordillera de la Costa in Venezuela, absent from the Andes, from c. 600–3200 m. (Fig. 20).

Nuevo W. de Cerro de Humo, 700–750 m, 7 August 1966, Steyermark & Rabe 96140 (B, NY, US); Peninsula de Paria, cloud forest in tributary headwaters of Río Cumaná, SW of Cerro de Humo, vicinity of Manacal, 15 km (by air) NW of Irapa, 800 m, 62°39'W, 10°41'N, 29 November 1979, Steyermark & Liesner 120698 (NY).

Solanum trizygum is superficially similar to *S. conicum* of the eastern Amazon, and is very closely related to that species (see Fig. 8). It differs from *S. conicum* in its more lanceolate leaflets that are very shortly petiolate or sessile, and its more elongate fruit. The fruit of *S. trizygum* also resembles that of *S. savannense*, but is longer and has a more pronounced beak. *Solanum trizygum* is quite common locally in the cloud forests of Central America.

The distribution pattern of *S. trizygum*, occurring in Central America and in the cordillera de la Costa in Venezuela, is quite common in angiosperms (see Knapp, 1991b). This may be indicative of some dispersal in the past, but alternatively may support geological hypotheses linking the Cordillera de la Costa with the Pacific plate (see Knapp, 1991b for a discussion).

10. *Solanum uleanum* Bitter in *Reprint nov. Spec. Regni veg.* 12: 139, pl. I (1913). Type: Brazil, Acre, Rio Acre, Porto Carlos, February 1911, Ule s.n. (B-syntype, destroyed; G!-lectotype). Both of the syntypes (*Ule* s.n. from Porto Carlos and *Ule* s.n. from San Francisco) cited by Bitter were destroyed at B. The collection from Porto Carlos is represented in the herbarium at G by a duplicate annotated in Bitter's hand that matches the plate accompanying the original description. The second syntype, *Ule* s.n. collected in June 1911 at San Francisco may be the same specimen as the type of var. *unipedunculatum* below. The numbering and dating of Ule's collections is occasionally somewhat confused.

Figs 2b, 4c, 22.

Solanum uleanum var. *unipedunculatum* Bitter in *Reprint nov. Spec. Regni veg.* 12: 140 (1913). Type: Brazil, Acre, San Francisco, May 1911, Ule 9756 (B holotype?, destroyed; K!-lectotype).

Solanum uleanum var. *gracilescens* Bitter in *Reprint nov. Spec. Regni veg.* 12: 141 (1913). Type: Peru, San Martín, Cerro Campana, December 1855, Spruce 4462 (K!-holotype).

Creeping herb, often tightly adhering to tree trunks and fallen logs, attaining up to 6 or 7 m in length. *Stems* c. 5 mm in diameter, copiously rooting at and between the nodes, pale greenish white, sparsely to densely pubescent with simple, uniseriate 5–6-celled trichomes 0.5–1 mm long, drying cateniforme. *Leaves* 3–15 × 2.5–10 cm, pinnate, elliptic, with 3–7 pairs of leaflets, the petiole 0.8–6 cm long; rachis of leaf minutely winged, especially between the terminal leaflet and the ultimate pair, sparsely to densely pubescent with trichomes like those of the stem; lateral leaflets elliptic, 1.5–6 × 0.4–2 cm, sparsely to densely pubescent with simple uniseriate trichomes like those of the stems, these denser adaxially, especially along the veins, the base attenuate, winged onto the rachis, petiolule c. 2 mm long, the apex obtuse to rounded; basal pair of leaflets smaller than the laterals, the apex more rounded; terminal leaflet equal in size to the laterals, elliptic to obovate, strongly winged onto the rachis. *Inflorescence* 1–10 cm long, axillary, occasionally 2–3 separate rachis arising from a single axil, occasionally branched, with 3–4 open flowers at a time, with up to 100 scars unevenly spaced c. 0.5 mm apart, sparsely to densely pubescent with simple uniseriate trichomes 0.5–1 mm long, drying white. *Buds* c. 3 mm in diameter, globose soon becoming ellipsoid, strongly exserted from the minute calyx tube. *Pedicels* at anthesis 0.5–0.7 cm long, filiform, nodding, sparsely pubescent like the rest of the inflorescence.

Flowers with the calyx tube c. 0.5 mm long, conical, the lobes 0.5 × 0.5–0.75 mm, quadrate with an apical projection, sparsely to densely pubescent with simple uniseriate trichomes, these denser on the apical projection; corolla 6–10 mm in diameter, greenish white, lobed nearly to the base, the lobes somewhat cucullate and slightly reflexed at anthesis, minutely papillose at the tips and along the margins; anthers 1.5–2.5 × 1–1.2 mm, poricidal at the tips, the pores lengthening to slits, free portion of the filaments c. 0.5 mm long, the filament tube minute and glabrous; ovary glabrous, conical; style 3–4 mm long, straight, densely long-papillose in the lower 1/2; stigma capitate. *Fruit* a conical, green berry, 1–1.2 × 1.5–1.6 cm, the beak c. 5 mm long and not containing seeds, truncate at the tip; fruiting pedicel 0.8–1 cm long, hanging. *Seeds* c. 20 per berry, 3–3.5 × 1.5–2.5 mm ovoid-reniform, greyish green to grey-brown; epidermal cell walls sinuous, thickened but without projections.

COMMON NAMES AND USES. ‘pupu huasca’ (Kohn 1102 – used medicinally by mother to prevent bleeding from umbilical cord of baby), ‘yana barabacha panga’ (Shemlück & Ness 174 – mashed leaves applied to wound like hydrogen peroxide, juice also used [Quechua]), ‘ofa kihi’ (Vickers 143 – remedy for diarrhoea, plant crushed and mixed with water [Cofan]), ‘ahi inta ikó’ (Vickers 273 – for stomach ache [Siona]).

DISTRIBUTION. Eastern slopes of the Andes from central Ecuador to central Peru, from 200–1200 m elevation, usually growing in primary forest or at the edges of clearings (Fig. 23).

SPECIMENS EXAMINED

ECUADOR. Napo: Parque Nacional Yasuní, Pozo petrolero Daimi 2, 200 m, 76°11'W, 00°55'S, 26 May 1988, Cerón & Hurtado 4057 (MO, NY, QCNE); Carretera Hollín-Loreto-Coca, km 40, entre Río Guamaní y Río Pucuno, 1200 m, 77°00'W, 00°40'S, 11 December 1987, Neill et al. 8107 (MO, NY), Cerón 2931 (MO, NY), Palacios 2219 (MO); Cantón Tena, Río Blanco community, headwaters of Río Huambuno, 6 km NNW of Ahuano, 440 m, 77°40'W, 01°00'S, 19 February 1990, Kohn 1102 (QCNE). **Pastaza:** Río Chicó, affluent of Río Pastaza, village of Río Chicó and vicinity, c. 10 km S. of Puyo, 3 km S. of Tarqui, 1000 m, 77°55'W, 01°03'S, August 1979, Shemlück & Ness 174 (F). **Sucumbíos:** Río Aguarico, Shushufindi, 23 February 1975, Vickers 143 (F); Shushufindi, 18 July 1979, Vickers 273 (F); San Pablo de los Secoyas, 300 m, 76°21'W, 00°15'S, 4 August 1981, Brandyge et al. 32965 (AAU).

Ucayali: Trail from Quebrada Shesha, (tributary of Río Abuja) to base of Cerro Las Cachoeiras, c. 70 km NE of Pucallpa, 300–400 m, 73°55'W, 8°02'S, 24 June 1987, Gentry & Díaz 58484 (MO, USM).

Solanum uleanum is certainly one of the most beautiful of the species of section *Pteroidea*. Its small size and peculiar (but found elsewhere in the section, see *S. anceps*) creeping habit make it conspicuously different from the other pinnate-leaved species. Even so, it can be difficult to distinguish on the herbarium sheet. *Solanum uleanum* differs from *S. conicum* and *S. mite* (both of which are sympatric with *S. uleanum*) in its more rounded, smaller leaflets which are more winged onto the rachis (i.e. without a petiolule) than in other pinnate species and greenish flowers. Fruiting specimens of *S. uleanum* are very rare, but its fruit, with an elongate non-seed-bearing beak is distinctive.

As with almost all other members of the section, *Solanum uleanum* possesses great variability in pubescence density. The type specimen (a photograph in the original publication and the lectotype at G) is densely hairy, while other collections are almost glabrous. There appear to be no environmental factors influencing this, but more detailed field studies could help clarify the situation. *Solanum uleanum* often grows up trees at the edge of gaps or clearings in the forest, and individuals growing in the deep shade of the understory have much thinner, more membranous leaves.

EXCLUDED SPECIES

1. ***Solanum cormanthum*** Vell. (synonym of *S. caavurana* Vell. = section *Geminata* (G. Don) Walp.)
2. ***Solanum lacteum*** Vell. (affinities and identification unknown, no type specimen exists and plate in Vellozo resembles no known species of *Solanum*)
3. ***Solanum laurinum*** Dunal (synonym of *S. decorticans* Sendtn. = section *Lysiphellos* Bitter)
4. ***Solanum loxophyllum*** Bitter (= section *Anarrhicomenum* Bitter)
5. ***Solanum marantifolium*** Bitter (= section *Geminata* (G. Don) Walp.)
6. ***Solanum pentaphyllum*** Bitter (= section *Herpystichum* Bitter)
7. ***Solanum robustifrons*** Bitter (= section *Geminata* (G. Don) Walp.)

ACKNOWLEDGMENTS. Many people have helped us in the course of this study, but we would particularly like to thank the following: both the late M.D. Whalen and the late T. Plowman for their inspiration in the study of solanums; D. Neill and T. Núñez of QCNE and P. Wilson for help and support in Ecuador; B. León, G. Lamas and the people of Tarapoto for help and support in Peru; S. France for the illustrations; the staff of the EM Unit at The Natural History Museum for technical help; the staff at the Photographic Unit of The Natural History Museum, especially C. Keates and D. Adams; V. Persson and J.R. Press of the Botany Department of The Natural History

Museum for help with illustrations: K. Adamson, A. Hume, and E. Smith for help with labelling and returning loans; J. Wheeler for carefully checking the exsiccatae; N. Turland for help with the databases; and J. Mallet for being the senior author's constant field companion. We would also like to thank the curators of the herbaria cited in the text for loan of specimens, and for permission to sample seeds from the specimens in their care.
